When transition metals are oxidized, *they lose their outer s electrons before they lose electrons from the d subshell.* (Section 7.4) The electron configuration of Fe is $[Ar]3d^64s^2$, for example, whereas that of Fe^{2+} is $[Ar]3d^6$. Formation of Fe^{3+} requires loss of one 3*d* electron, giving $[Ar]3d^5$. Most transition-metal ions contain partially occupied *d* subshells, which are responsible in large part for three characteristics:

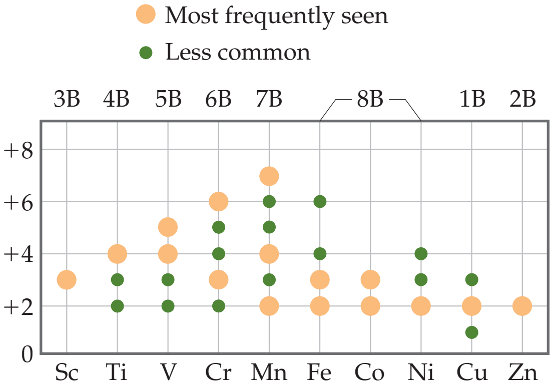
1. Transition metals often have more than one stable oxidation state.
2. Many transition-metal compounds are colored, as shown in ▲ Figure 23.4.
3. Transition metals and their compounds often exhibit magnetic properties.

◀ Figure 23.5 shows the common nonzero oxidation states for the period 4 transition metals. The +2 oxidation state, which is common for most transition metals, is due to the loss of the two outer 4*s* electrons. This oxidation state is found for all these elements except Sc, where the 3+ ion with an [Ar] configuration is particularly stable.

Oxidation states above +2 are due to successive losses of 3*d* electrons. From Sc through Mn the maximum oxidation state increases from +3 to +7, equaling in each case the total number of 4*s* plus 3*d* electrons in the atom. Thus, manganese has a maximum oxidation state of 2 + 5 = +7. As we move to the right beyond Mn in Figure 23.5, the maximum oxidation state decreases. This decrease is due in part to the attraction of *d* orbital electrons to the nucleus, which increases faster than the attraction of the *s* orbital electrons to the nucleus as we move left to right across the periodic table. In other words, in each period the *d* electrons become more corelike as the atomic number increases. By the time we get to zinc, it is not possible to remove electrons from the 3*d* orbitals through chemical oxidation.

GO FIGURE

For which of the ions shown in this figure are the 4*s* orbitals empty? For which ions are the 3*d* orbitals empty?



▲ **Figure 23.5** **Nonzero oxidation states of the period 4 transition metals.**

In the transition metals of periods 5 and 6, the increased size of the 4*d* and 5*d* orbitals makes it possible to attain maximum oxidation states as high as +8, which is achieved in RuO_4 and OsO_4. In general, the maximum oxidation states are found only when the metals are combined with the most electronegative elements, especially O, F, and in some cases Cl.

Give It Some Thought

Why does Ti^{5+} not exist?

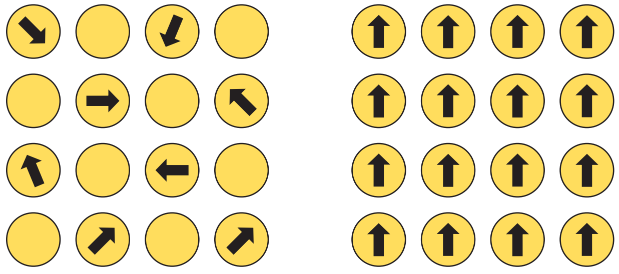
Magnetism

The spin an electron possesses gives the electron a *magnetic moment*, a property that causes the electron to behave like a tiny magnet. In a *diamagnetic* solid, defined as one in which all the electrons in the solid are paired, the spin-up and spin-down electrons cancel one another. (Section 9.8) Diamagnetic substances are generally described as being nonmagnetic, but when a diamagnetic substance is placed in a magnetic field, the motions of the electrons cause the substance to be very weakly repelled by the magnet. In other words, these supposedly nonmagnetic substances do show some very faint magnetic character in the presence of a magnetic field.

A substance in which the atoms or ions have one or more unpaired electrons is *paramagnetic*. (Section 9.8) In a paramagnetic solid, the electrons on one atom or ion do not influence the unpaired electrons on neighboring atoms or ions. As a result, the magnetic moments on the atoms or ions are randomly oriented and constantly changing direction, as shown in ▶ Figure 23.6(a). When a paramagnetic substance is placed in a magnetic field, however, the magnetic moments tend to align parallel to one another, producing a net attractive interaction with the magnet. Thus, unlike a diamagnetic substance, which is weakly repulsed by a magnetic field, a paramagnetic substance is attracted to a magnetic field.

GO FIGURE

Describe how the representation shown for the paramagnetic material would change if the material were placed in a magnetic field.

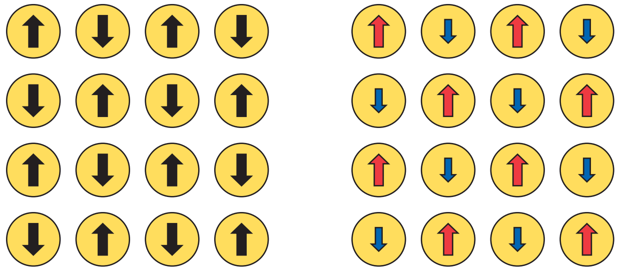


Paramagnetic; spins random; spins do align if in a magnetic field

(a)

Ferromagnetic; spins aligned parallel to each other

(b)



Antiferromagnetic; spins align in opposite directions and cancel each other

(c)

Ferrimagnetic; unequal spins align in opposite directions but do not completely cancel each other

(d)

▲ Figure 23.6 **The relative orientation of electron spins in various types of magnetic substances.**

When you think of a magnet, you probably picture a simple iron magnet. Iron exhibits **ferromagnetism**, a form of magnetism much stronger than paramagnetism. Ferromagnetism arises when the unpaired electrons of the atoms or ions in a solid are influenced by the orientations of the electrons in neighboring atoms or ions. The most stable (lowest-energy) arrangement is when the spins of electrons on adjacent atoms or ions are aligned in the same direction, as in Figure 23.6(b). When a ferromagnetic solid is placed in a magnetic field, the electrons tend to align strongly in a direction parallel to the magnetic field. The attraction to the magnetic field that results may be as much as one million times stronger than that for a paramagnetic substance.

When a ferromagnet is removed from an external magnetic field, the interactions between the electrons cause the ferromagnetic substance to maintain a magnetic moment. We then refer to it as a *permanent magnet* (▶ Figure 23.7).

▲ Figure 23.7 **A permanent magnet.** Permanent magnets are made from ferromagnetic and ferrimagnetic materials.

The only ferromagnetic transition metals are Fe, Co, and Ni, but many alloys also exhibit ferromagnetism, which is in some cases stronger than the ferromagnetism of the pure metals. Particularly powerful ferromagnetism is found in compounds containing both transition metals and lanthanide metals. Two of the most important examples are $SmCo_5$ and $Nd_2Fe_{14}B$.

Two additional types of magnetism involving ordered arrangements of unpaired electrons are depicted in Figure 23.6. In materials that exhibit **antiferromagnetism** [Figure 23.6(c)], the unpaired electrons on a given atom or ion align so that their spins are oriented in the direction opposite the spin direction on neighboring atoms.

This means that the spin-up and spin-down electrons cancel each other. Examples of antiferromagnetic substances are chromium metal, FeMn alloys, and such transition-metal oxides as Fe_2O_3, $LaFeO_3$, and MnO.

A substance that exhibits **ferrimagnetism** [Figure 23.6(d)] has both ferromagnetic and antiferromagnetic characteristics. Like an antiferromagnet, the unpaired electrons align so that the spins in adjacent atoms or ions point in opposite directions. However, unlike an antiferromagnet, the net magnetic moments of the spin-up electrons are not fully canceled by the spin-down electrons. This can happen because the magnetic centers have different numbers of unpaired electrons ($NiMnO_3$), because the number of magnetic sites aligned in one direction is larger than the number aligned in the other direction ($Y_3Fe_5O_{12}$), or because both these conditions apply (Fe_3O_4). Because the magnetic moments do not cancel, the properties of ferrimagnetic materials are similar to the properties of ferromagnetic materials.

Give It Some Thought

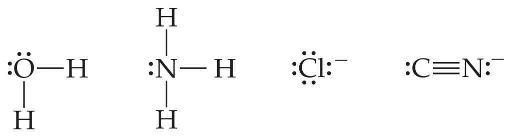
How do you think spin–spin interactions of unpaired electrons on adjacent atoms in a substance are affected by the interatomic distance?

Ferromagnets, ferrimagnets, and antiferromagnets all become paramagnetic when heated above a critical temperature. This happens when the thermal energy is sufficient to overcome the forces determining the spin directions of the electrons. This temperature is called the *Curie temperature*, T_C, for ferromagnets and ferrimagnets and the *Néel temperature*, T_N, for antiferromagnets.

23.2 | Transition-Metal Complexes

The transition metals occur in many interesting and important molecular forms. Species that are assemblies of a central transition-metal ion bonded to a group of surrounding molecules or ions, such as $[Ag(NH_3)_2]^+$ and $[Fe(H_2O)_6]^{3+}$, are called **metal complexes**, or merely *complexes*.* If the complex carries a net charge, it is generally called a *complex ion*. (Section 17.5) Compounds that contain complexes are known as **coordination compounds**.

The molecules or ions that bond to the metal ion in a complex are known as **ligands** (from the Latin word *ligare*, "to bind"). There are two NH_3 ligands bonded to Ag^+ in the complex ion $[Ag(NH_3)_2]^+$, for instance, and six H_2O ligands bonded to Fe^{3+} in $[Fe(H_2O)_6]^{3+}$. Each ligand functions as a Lewis base and so donates a pair of electrons to form the ligand–metal bond. (Section 16.11) Thus, every ligand has at least one unshared pair of valence electrons. Four of the most frequently encountered ligands,



$$:\ddot{\mathrm{O}}\!-\!\mathrm{H}\ \text{(with H below O)} \qquad :\mathrm{N}\!-\!\mathrm{H}\ \text{(with H above and below N)} \qquad :\ddot{\underset{\cdot\cdot}{\mathrm{Cl}}}:^- \qquad :\mathrm{C}\!\equiv\!\mathrm{N}:^-$$

illustrate that most ligands are either polar molecules or anions. In forming a complex, the ligands are said to *coordinate* to the metal.

Give It Some Thought

Is the interaction between an ammonia ligand and a metal cation a Lewis acid–base interaction? If so, which species acts as the Lewis acid?

---

*Most of the coordination compounds we examine in this chapter contain transition-metal ions, although ions of other metals can also form complexes.

The Development of Coordination Chemistry: Werner's Theory

Because compounds of the transition metals are beautifully colored, the chemistry of these elements fascinated chemists even before the periodic table was introduced. During the late 1700s through the 1800s, the many coordination compounds that were isolated and studied had properties that were puzzling in light of the bonding theories prevailing at the time. ▼ **Table 23.3**, for example, lists a series of $CoCl_3$–NH_3 compounds that have strikingly different colors. Note that the third and fourth species have different colors even though the originally assigned formula was the same for both, $CoCl_3 \cdot 4\,NH_3$.

The modern formulations of the compounds in Table 23.3 are based on various lines of experimental evidence. For example, all four compounds are strong electrolytes (Section 4.1) but yield different numbers of ions when dissolved in water. Dissolving $CoCl_3 \cdot 6\,NH_3$ in water yields four ions per formula unit ($[Co(NH_3)_6]^{3+}$ plus three Cl^- ions), whereas $CoCl_3 \cdot 5\,NH_3$ yields only three ions per formula unit ($[Co(NH_3)_5Cl]^{2+}$ and two Cl^- ions). Furthermore, the reaction of the compounds with excess aqueous silver nitrate leads to the precipitation of different amounts of $AgCl(s)$. When $CoCl_3 \cdot 6\,NH_3$ is treated with excess $AgNO_3(aq)$, 3 mol of $AgCl(s)$ precipitate per mole of complex, which means all three Cl^- ions in the complex can react to form $AgCl(s)$. By contrast, when $CoCl_3 \cdot 5\,NH_3$ is treated with excess $AgNO_3(aq)$, only 2 mol of $AgCl(s)$ precipitate per mole of complex, telling us that one of the Cl^- ions in the complex does not react. These results are summarized in Table 23.3.

In 1893 the Swiss chemist Alfred Werner (1866–1919) proposed a theory that successfully explained the observations in Table 23.3. In a theory that became the basis for understanding coordination chemistry, Werner proposed that any metal ion exhibits both a primary valence and a secondary valence. The *primary valence* is the oxidation state of the metal, which is +3 for the complexes in Table 23.3. (Section 4.4) The *secondary valence* is the number of atoms bonded to the metal ion, which is also called the **coordination number**. For these cobalt complexes, Werner deduced a coordination number of 6 with the ligands in an octahedral arrangement around the Co^{3+} ion.

Werner's theory provided a beautiful explanation for the results in Table 23.3. The NH_3 molecules are ligands bonded to the Co^{3+} ion (through the nitrogen atom as we will see later); if there are fewer than six NH_3 molecules, the remaining ligands are Cl^- ions. The central metal and the ligands bound to it constitute the **coordination sphere** of the complex.

In writing the chemical formula for a coordination compound, Werner suggested using square brackets to signify the makeup of the coordination sphere in any given compound. He therefore proposed that $CoCl_3 \cdot 6\,NH_3$ and $CoCl_3 \cdot 5\,NH_3$ are better written as $[Co(NH_3)_6]Cl_3$ and $[Co(NH_3)_5Cl]Cl_2$, respectively. He further proposed that the chloride ions that are part of the coordination sphere are bound so tightly that they do not dissociate when the complex is dissolved in water. Thus, dissolving $[Co(NH_3)_5Cl]Cl_2$ in water produces a $[Co(NH_3)_5Cl]^{2+}$ ion and two Cl^- ions.

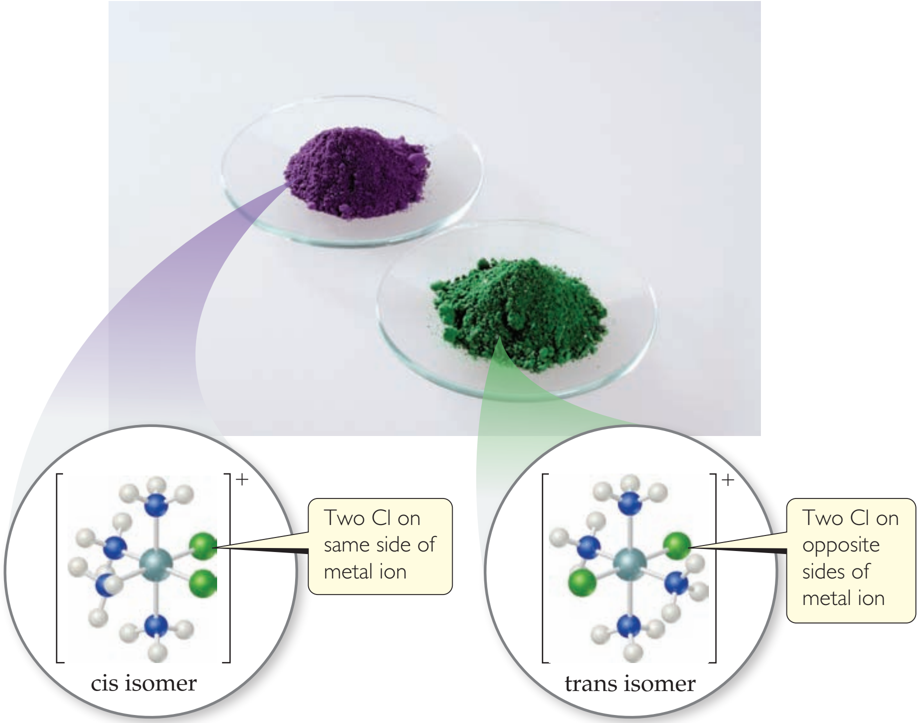
Werner's ideas also explained why there are two forms of $CoCl_3 \cdot 4\,NH_3$. Using Werner's postulates, we write the formula as $[Co(NH_3)_4Cl_2]Cl$. As shown in **Figure 23.8**, there are two ways to arrange the ligands in the $[Co(NH_3)_4Cl_2]^+$ complex, called the *cis* and *trans* forms. In the cis form, the two chloride ligands occupy adjacent vertices of the octahedral arrangement. In *trans*-$[Co(NH_3)_4Cl_2]^+$ the two chlorides are opposite

Table 23.3 Properties of Some Ammonia Complexes of Cobalt(III)

Original Formulation	Color	Ions per Formula Unit	"Free" Cl^- Ions per Formula Unit	Modern Formulation
$CoCl_3 \cdot 6\,NH_3$	Orange	4	3	$[Co(NH_3)_6]Cl_3$
$CoCl_3 \cdot 5\,NH_3$	Purple	3	2	$[Co(NH_3)_5Cl]Cl_2$
$CoCl_3 \cdot 4\,NH_3$	Green	2	1	*trans*-$[Co(NH_3)_4Cl_2]Cl$
$CoCl_3 \cdot 4\,NH_3$	Violet	2	1	*cis*-$[Co(NH_3)_4Cl_2]Cl$

GO FIGURE

Is there another way to arrange the chloride ions in the $[Co(NH_3)_4Cl_2]^+$ ion besides the two shown in this figure?



+

▲ **Figure 23.8** **Isomers of $[Co(NH_3)_4Cl_2]^+$.** The cis isomer is violet, and the trans isomer is green.

each other. It is this difference in positions of the Cl ligands that leads to two compounds, one violet and one green.

The insight Werner provided into the bonding in coordination compounds is even more remarkable when we realize that his theory predated Lewis's ideas of covalent bonding by more than 20 years! Because of his tremendous contributions to coordination chemistry, Werner was awarded the 1913 Nobel Prize in Chemistry.

SAMPLE EXERCISE 23.1 Identifying the Coordination Sphere of a Complex

Palladium(II) tends to form complexes with coordination number 4. A compound has the composition $PdCl_2 \cdot 3\,NH_3$. **(a)** Write the formula for this compound that best shows the coordination structure. **(b)** When an aqueous solution of the compound is treated with excess $AgNO_3(aq)$, how many moles of $AgCl(s)$ are formed per mole of $PdCl_2 \cdot 3\,NH_3$?

SOLUTION

Analyze We are given the coordination number of Pd(II) and a chemical formula indicating that the complex contains NH_3 and Cl^-. We are asked to determine **(a)** which ligands are attached to Pd(II) in the compound and **(b)** how the compound behaves toward $AgNO_3$ in aqueous solution.

Plan **(a)** Because of their charge, the Cl^- ions can be either in the coordination sphere, where they are bonded directly to the metal, or outside the coordination sphere, where they are bonded ionically to the complex. The electrically neutral NH_3 ligands must be in the coordination sphere, if we assume four ligands bonded to the Pd(II) ion. **(b)** Any chlorides in the coordination sphere do not precipitate as AgCl.

Solve

(a) By analogy to the ammonia complexes of cobalt(III) shown in Figure 23.7, we predict that the three NH_3 are ligands attached to the Pd(II) ion. The fourth ligand around Pd(II) is one chloride ion. The second chloride ion is not a ligand; it serves only as a *counterion* (a noncoordinating ion that balances charge) in the compound. We conclude that the formula showing the structure best is $[Pd(NH_3)_3Cl]Cl$.

(b) Because only the non-ligand Cl^- can react, we expect to produce 1 mol of AgCl(*s*) per mole of complex. The balanced equation is

$$[Pd(NH_3)_3Cl]Cl(aq) + AgNO_3(aq) \longrightarrow [Pd(NH_3)_3Cl]NO_3(aq) + AgCl(s)$$

This is a metathesis reaction (Section 4.2) in which one of the cations is the $[Pd(NH_3)_3Cl]^+$ complex ion.

Practice Exercise 1

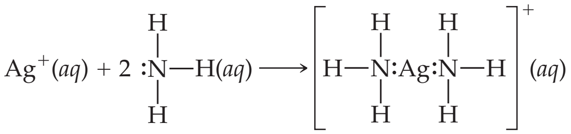
When the compound $RhCl_3 \cdot 4\,NH_3$ is dissolved in water and treated with excess $AgNO_3(aq)$ one mole of AgCl(*s*) is formed for every mole of $RhCl_3 \cdot 4\,NH_3$. What is the correct way to write the formula of this compound? **(a)** $[Rh(NH_3)_4Cl_3]$, **(b)** $[Rh(NH_3)_4Cl_2]Cl$, **(c)** $[Rh(NH_3)_4Cl]Cl_2$, **(d)** $[Rh(NH_3)_4]Cl_3$, **(e)** $[RhCl_3](NH_3)_4$.

Practice Exercise 2

Predict the number of ions produced per formula unit when the compound $CoCl_2 \cdot 6\,H_2O$ dissolves in water to form an aqueous solution.

The Metal–Ligand Bond

The bond between a ligand and a metal ion is a Lewis acid–base interaction. (Section 16.11) Because the ligands have available pairs of electrons, they can function as Lewis bases (electron-pair donors). Metal ions (particularly transition-metal ions) have empty valence orbitals, so they can act as Lewis acids (electron-pair acceptors). We can picture the bond between the metal ion and ligand as the result of their sharing a pair of electrons initially on the ligand:

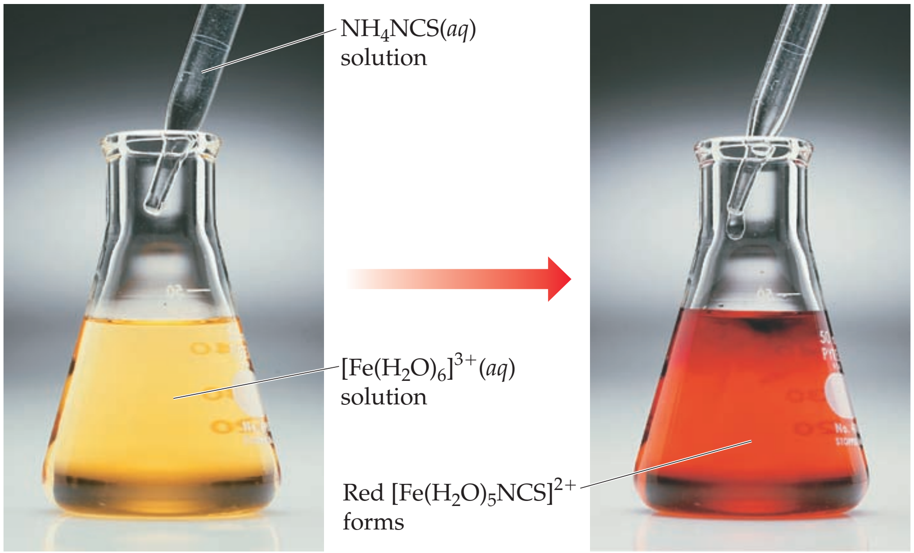


$$Ag^+(aq) + 2\,:NH_3(aq) \longrightarrow [H_3N:Ag:NH_3]^+(aq) \qquad [23.1]$$

The formation of metal–ligand bonds can markedly alter the properties we observe for the metal ion. A metal complex is a distinct chemical species that has physical and chemical properties different from those of the metal ion and ligands from which it is formed. As one example, ▼ Figure 23.9 shows the color change that occurs when aqueous solutions of NCS^- (colorless) and Fe^{3+} (yellow) are mixed, forming $[Fe(H_2O)_5NCS]^{2+}$.

GO FIGURE

Write a balanced chemical equation for the reaction depicted in this figure.



$NH_4NCS(aq)$ solution
$[Fe(H_2O)_6]^{3+}(aq)$ solution
Red $[Fe(H_2O)_5NCS]^{2+}$ forms

▲ Figure 23.9 **Reaction of $Fe^{3+}(aq)$ and $NCS^-(aq)$.**

Complex formation can also significantly change other properties of metal ions, such as their ease of oxidation or reduction. Silver ion, for example, is readily reduced in water,

$$\mathrm{Ag^+}(aq) + \mathrm{e^-} \longrightarrow \mathrm{Ag}(s) \qquad E^\circ = +0.799\ \mathrm{V} \qquad [23.2]$$

but the $[\mathrm{Ag(CN)_2}]^-$ ion is not so easily reduced because complexation by $\mathrm{CN^-}$ ions stabilizes silver in the +1 oxidation state:

$$[\mathrm{Ag(CN)_2}]^-(aq) + \mathrm{e^-} \longrightarrow \mathrm{Ag}(s) + 2\,\mathrm{CN^-}(aq) \quad E^\circ = -0.31\ \mathrm{V} \qquad [23.3]$$

Hydrated metal ions are complexes in which the ligand is water. Thus, $\mathrm{Fe^{3+}}(aq)$ consists largely of $[\mathrm{Fe(H_2O)_6}]^{3+}$. (Section 16.11) It is important to realize that ligands can undergo reaction. For example, we saw in Figure 16.16 that a water molecule in $[\mathrm{Fe(H_2O)_6}]^{3+}(aq)$ can be deprotonated to yield $[\mathrm{Fe(H_2O)_5OH}]^{2+}(aq)$ and $\mathrm{H^+}(aq)$. The iron ion retains its oxidation state; the coordinated hydroxide ligand, with a 1− charge, reduces the complex charge to 2+. Ligands can also be displaced from the coordination sphere by other ligands, if the incoming ligands bind more strongly to the metal ion than the original ones. For example, ligands such as $\mathrm{NH_3}$, $\mathrm{NCS^-}$, and $\mathrm{CN^-}$ can replace $\mathrm{H_2O}$ in the coordination sphere of metal ions.

Charges, Coordination Numbers, and Geometries

The charge of a complex is the sum of the charges on the metal and on the ligands. In $[\mathrm{Cu(NH_3)_4}]\mathrm{SO_4}$ we can deduce the charge on the complex ion because we know that the charge of the sulfate ion is 2−. Because the compound is electrically neutral, the complex ion must have a 2+ charge, $[\mathrm{Cu(NH_3)_4}]^{2+}$. We can then use the charge of the complex ion to deduce the oxidation number of copper. Because the $\mathrm{NH_3}$ ligands are uncharged molecules, the oxidation number of copper must be +2:

$$\begin{array}{c} +2 + 4(0) = +2 \\ \downarrow \qquad \downarrow \qquad \swarrow \\ [\mathrm{Cu(NH_3)_4}]^{2+} \end{array}$$

SAMPLE EXERCISE 23.2 Determining the Oxidation Number of a Metal in a Complex

What is the oxidation number of the metal in $[\mathrm{Rh(NH_3)_5Cl}](\mathrm{NO_3})_2$?

SOLUTION

Analyze We are given the chemical formula of a coordination compound and asked to determine the oxidation number of its metal atom.

Plan To determine the oxidation number of Rh, we need to figure out what charges are contributed by the other groups. The overall charge is zero, so the oxidation number of the metal must balance the charge due to the rest of the compound.

Solve The $\mathrm{NO_3}$ group is the nitrate anion, which has a 1− charge. The $\mathrm{NH_3}$ ligands carry zero charge, and the Cl is a coordinated chloride ion, which has a 1− charge. The sum of all the charges must be zero:

$$\begin{array}{c} x + 5(0) + (-1) + 2(-1) = 0 \\ \searrow \quad \downarrow \quad \downarrow \quad \swarrow \\ [\mathrm{Rh(NH_3)_5Cl}](\mathrm{NO_3})_2 \end{array}$$

The oxidation number of rhodium, x, must therefore be +3.

Practice Exercise 1

In which of the following compounds does the transition-metal have the highest oxidation number? **(a)** $[\mathrm{Co(NH_3)_4Cl_2}]$, **(b)** $\mathrm{K_2[PtCl_6]}$, **(c)** $\mathrm{Rb_3[MoO_3F_3]}$, **(d)** $\mathrm{Na[Ag(CN)_2]}$, **(e)** $\mathrm{K_4[Mn(CN)_6]}$.

Practice Exercise 2

What is the charge of the complex formed by a platinum(II) metal ion surrounded by two ammonia molecules and two bromide ions?

Recall that the number of atoms directly bonded to the metal atom in a complex is the *coordination number* of the complex. Thus, the silver ion in $[\mathrm{Ag(NH_3)_2}]^+$ has a coordination number of 2, and the cobalt ion has a coordination number of 6 in all four complexes in Table 23.3.

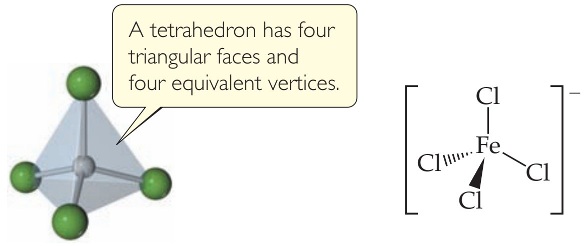
Some metal ions have only one observed coordination number. The coordination number of chromium(III) and cobalt(III) is invariably 6, for example, and that of platinum(II) is always 4. For most metals, however, the coordination number is different for different ligands. In these complexes, the most common coordination numbers are 4 and 6.

The coordination number of a metal ion is often influenced by the relative sizes of the metal ion and the ligands. As the ligand gets larger, fewer of them can coordinate to the metal ion. Thus, iron(III) is able to coordinate to six fluorides in $[FeF_6]^{3-}$ but to only four chlorides in $[FeCl_4]^-$. Ligands that transfer substantial negative charge to the metal also produce reduced coordination numbers. For example, six ammonia molecules can coordinate to nickel(II), forming $[Ni(NH_3)_6]^{2+}$, but only four cyanide ions can coordinate to this ion, forming $[Ni(CN)_4]^{2-}$.

The most common coordination geometries for coordination complexes are shown in ▶ Figure 23.10. Complexes in which the coordination number is 4 have two geometries—tetrahedral and square planar. The tetrahedral geometry is the more common of the two and is especially prevalent among nontransition metals. The square planar geometry is characteristic of transition-metal ions with eight *d* electrons in the valence shell, such as platinum(II) and gold(III). Complexes with a coordination number of 6 almost always have an octahedral geometry. Even though the octahedron can be drawn as a square with one ligand above and another below the plane, all six vertices are equivalent.

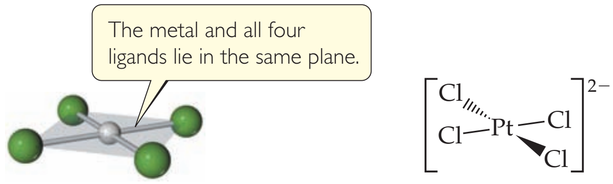
GO FIGURE

In the drawings on the right-hand side, what does the solid wedge connecting atoms represent? What does the dashed wedge connecting atoms represent?



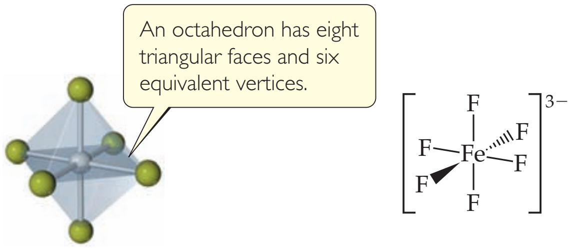
A tetrahedron has four triangular faces and four equivalent vertices.

Tetrahedral geometry



The metal and all four ligands lie in the same plane.

Square planar geometry



An octahedron has eight triangular faces and six equivalent vertices.

Octahedral geometry

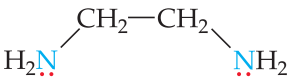
▲ Figure 23.10 **Common geometries of coordination complexes.** In complexes having coordination number 4, the geometry is typically either tetrahedral or square planar. In complexes having coordination number 6, the geometry is nearly always octahedral.

23.3 | Common Ligands in Coordination Chemistry

The ligand atom that binds to the central metal ion in a coordination complex is called the **donor atom** of the ligand. Ligands having only one donor atom are called **monodentate ligands** (from the Latin, meaning "one-toothed"). These ligands are able to occupy only one site in a coordination sphere. Ligands having two donor atoms are **bidentate ligands** ("two-toothed"), and those having three or more donor atoms are **polydentate ligands** ("many-toothed"). In both bidentate and polydentate species, the multiple donor atoms can simultaneously bond to the metal ion, thereby occupying two or more sites in a coordination sphere. Table 23.4 gives examples of all three types of ligands.

Because they appear to grasp the metal between two or more donor atoms, bidentate and polydentate ligands are also known as **chelating agents** (pronounced "KEE-lay-ting"; from the Greek *chele*, "claw").

One common chelating agent is the bidentate ligand *ethylenediamine*, denoted en:



in which each donor nitrogen atom has one nonbonding electron pair. These donor atoms are sufficiently far apart to allow both of them to bond to the metal ion in adjacent positions. The $[Co(en)_3]^{3+}$ complex ion, which contains three ethylenediamine ligands in the octahedral coordination sphere of cobalt(III), is shown in Figure 23.11. Notice that in the image on the right the en is written in a shorthand notation as two nitrogen atoms connected by an arc.

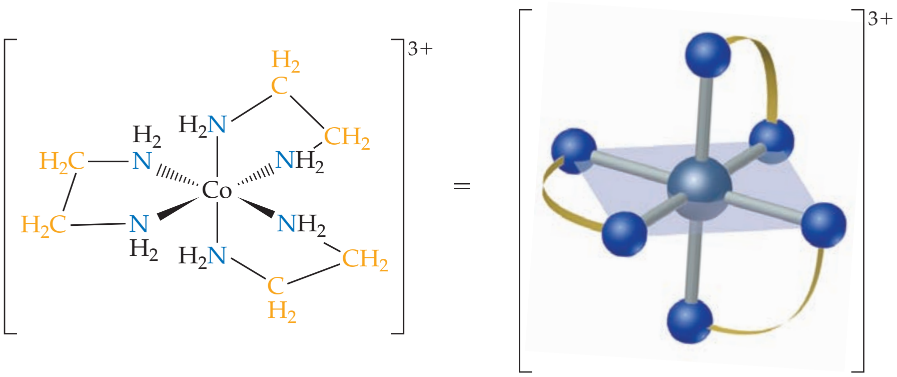
The ethylenediaminetetraacetate ion, $[EDTA]^{4-}$, is an important polydentate ligand that has six donor atoms. It can wrap around a metal ion using all six donor atoms, as shown in Figure 23.12, although it sometimes binds to a metal using only five of its donor atoms.

Give It Some Thought

Both H_2O and ethylenediamine (en) have two nonbonding pairs of electrons. Why cannot water act as a bidentate ligand?

Table 23.4 Some Common Ligands

Ligand Type	Examples				
Monodentate	$H_2\ddot{O}:$ Water	$:\ddot{F}:^-$ Fluoride ion	$[:C\equiv N:]^-$ Cyanide ion	$[:\ddot{O}-H]^-$ Hydroxide ion	
	$:NH_3$ Ammonia	$:\ddot{Cl}:^-$ Chloride ion	$\underbrace{[:\ddot{S}=C=\ddot{N}:]^-}_{\text{or}}$ Thiocyanate ion	$\underbrace{[:\ddot{O}-N=\ddot{O}:]^-}_{\text{or}}$ Nitrite ion	
Bidentate	 Ethylenediamine (en)	 Bipyridine (bipy or bpy)	 *Ortho*-phenanthroline (*o*-phen)	 Oxalate ion	 Carbonate ion
Polydentate	 Diethylenetriamine	 Triphosphate ion			
	 Ethylenediaminetetraacetate ion (EDTA^{4-})				



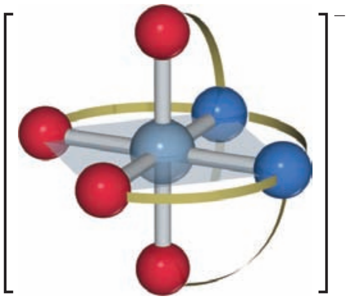
$[Co(en)_3]^{3+}$

▲ **Figure 23.11** **The $[Co(en)_3]^{3+}$ ion.** The ligand is ethylenediamine.

In general, the complexes formed by chelating ligands (that is, bidentate and polydentate ligands) are more stable than the complexes formed by related monodentate ligands. The equilibrium formation constants for $[Ni(NH_3)_6]^{2+}$ and $[Ni(en)_3]^{2+}$ illustrate this observation:

$$[Ni(H_2O)_6]^{2+}(aq) + 6\,NH_3(aq) \rightleftharpoons [Ni(NH_3)_6]^{2+}(aq) + 6\,H_2O(l) \qquad K_f = 1.2 \times 10^9 \qquad [23.4]$$

$$[Ni(H_2O)_6]^{2+}(aq) + 3\,en(aq) \rightleftharpoons [Ni(en)_3]^{2+}(aq) + 6\,H_2O(l) \qquad K_f = 6.8 \times 10^{17} \qquad [23.5]$$



▲ **Figure 23.12** **The complex ion $[Co(EDTA)]^-$.** The ligand is the polydentate ethylenediaminetetraacetate ion, whose full representation is given in Table 23.2. This representation shows how the two N and four O donor atoms coordinate to cobalt.

Although the donor atom is nitrogen in both instances, $[Ni(en)_3]^{2+}$ has a formation constant that is more than 10^8 times larger than that of $[Ni(NH_3)_6]^{2+}$. This trend of generally larger formation constants for bidentate and polydentate ligands, known as the **chelate effect**, is examined in the "A Closer Look" essay on page 1010.

Chelating agents are often used to prevent one or more of the customary reactions of a metal ion without removing the ion from solution. For example, a metal ion that interferes with a chemical analysis can often be complexed and its interference thereby removed. In a sense, the chelating agent hides the metal ion. For this reason, scientists sometimes refer to these ligands as *sequestering agents*.

Phosphate ligands, such as sodium tripolyphosphate, $Na_5[OPO_2OPO_2OPO_3]$, are used to sequester Ca^{2+} and Mg^{2+} ions in hard water so that these ions cannot interfere with the action of soap or detergents.

Chelating agents are used in many prepared foods, such as salad dressings and frozen desserts, to complex trace metal ions that catalyze decomposition reactions. Chelating agents are used in medicine to remove toxic heavy metal ions that have been ingested, such as Hg^{2+}, Pb^{2+}, and Cd^{2+}. One method of treating lead poisoning, for example, is to administer $Na_2Ca(EDTA)$. The EDTA chelates the lead, allowing it to be removed from the body via urine.

Give It Some Thought

Cobalt(III) has a coordination number of 6 in all its complexes. Is the carbonate ion a monodentate or bidentate ligand in the $[Co(NH_3)_4(CO_3)]^+$ ion?

Metals and Chelates in Living Systems

Ten of the 29 elements known to be necessary for human life are transition metals. (Section 2.7, "Elements Required by Living Organisms") These ten elements—V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Mo, and Cd—form complexes with a variety of groups present in biological systems.

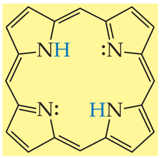
Although our bodies require only small quantities of metals, deficiencies can lead to serious illness. A deficiency of manganese, for example, can lead to convulsive disorders. Some epilepsy patients have been helped by the addition of manganese to their diets.

Among the most important chelating agents in nature are those derived from the *porphine* molecule (▶ **Figure 23.13**). This molecule can coordinate to a metal via its four nitrogen donor atoms. Once porphine bonds to a metal ion, the two H atoms on the nitrogens are displaced to form complexes called **porphyrins**. Two important porphyrins are *hemes*, in which the metal ion is Fe(II), and *chlorophylls*, with a Mg(II) central ion.

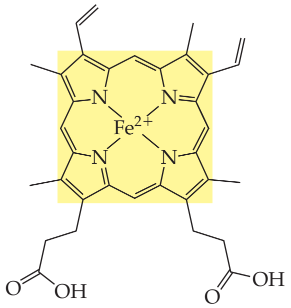
Figure 23.14 shows a schematic structure of myoglobin, a protein that contains one heme group. Myoglobin is a *globular protein*, one that folds into a compact, roughly spherical shape. Myoglobin is found in the cells of skeletal muscle, particularly in seals, whales, and porpoises. It stores oxygen in cells, one molecule of O_2 per myoglobin, until it is needed for metabolic activities. Hemoglobin, the protein that transports oxygen in human blood, is made up of four heme-containing subunits, each of which is very similar to myoglobin. One hemoglobin can bind up to four O_2 molecules.

GO FIGURE

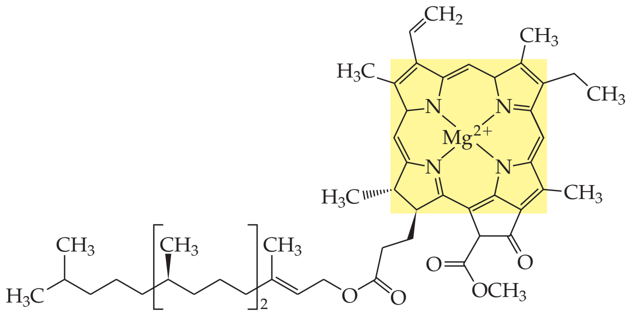
What is the coordination number of the metal ion in heme b? In chlorophyll a?



Porphine



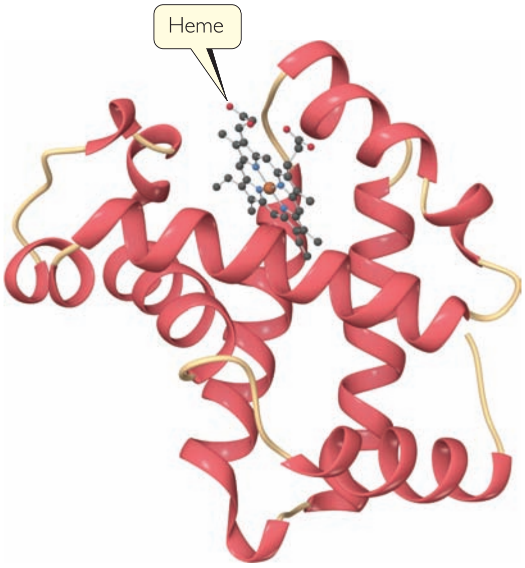
Heme b



Chlorophyll a

▲ **Figure 23.13 Porphine and two porphyrins, heme b and chlorophyll a.** Fe(II) and Mg(II) ions replace the two blue H atoms in porphine and bond with all four nitrogens in heme b and chlorophyll a, respectively.

In both myoglobin and hemoglobin, the iron is coordinated to the four nitrogen atoms of a porphyrin and to a nitrogen atom from the protein chain (**Figure 23.15**). In hemoglobin, the sixth position around the iron is occupied either by O_2 (in oxyhemoglobin, the bright red form) or by water (in deoxyhemoglobin, the purplish red form). (The oxy form is the one shown in Figure 23.15.)



▲ **Figure 23.14 Myoglobin.** This ribbon diagram does not show most of the atoms.

Carbon monoxide is poisonous because the equilibrium binding constant of human hemoglobin for CO is about 210 times greater than that for O_2. As a result, a relatively small quantity of CO can inactivate a substantial fraction of the hemoglobin in the blood by displacing the O_2 molecule from the heme-containing subunit. For example, a person breathing air that contains only 0.1% CO takes in enough CO after a few hours to convert up to 60% of the hemoglobin (Hb) into COHb, thereby reducing the blood's normal oxygen-carrying capacity by 60%.

Under normal conditions, a nonsmoker breathing unpolluted air has about 0.3 to 0.5% COHb in her or his blood. This amount arises mainly from the production of small quantities of CO in the course of normal body chemistry and from the small amount of CO present in clean air. Exposure to higher concentrations of CO causes the COHb level to increase, which in turn leaves fewer Hb sites to which O_2 can bind. If the level of COHb becomes too high, oxygen transport is effectively shut down and death occurs. Because CO is colorless and odorless, CO poisoning occurs with very little warning. Improperly ventilated combustion devices, such as kerosene lanterns and stoves, thus pose a potential health hazard.

A Closer Look

Entropy and the Chelate Effect

We learned in Section 19.5 that chemical processes are favored by positive entropy changes and by negative enthalpy changes. The special stability associated with the formation of chelates, called the *chelate effect*, can be explained by comparing the entropy changes that occur with monodentate ligands with the entropy changes that occur with polydentate ligands.

We begin with the reaction in which two H_2O ligands of the square-planar Cu(II) complex $[Cu(H_2O)_4]^{2+}$ are replaced by monodentate NH_3 ligands at 27 °C:

$$[Cu(H_2O)_4]^{2+}(aq) + 2\,NH_3(aq) \rightleftharpoons [Cu(H_2O)_2(NH_3)_2]^{2+}(aq) + 2\,H_2O(l)$$

$$\Delta H^\circ = -46\text{ kJ};\quad \Delta S^\circ = -8.4\text{ J/K};\quad \Delta G^\circ = -43\text{ kJ}$$

The thermodynamic data tell us about the relative abilities of H_2O and NH_3 to serve as ligands in this reaction. In general, NH_3 binds more tightly to metal ions than does H_2O, so this substitution reaction is exothermic ($\Delta H < 0$). The stronger bonding of the NH_3 ligands also causes the $[Cu(H_2O)_2(NH_3)_2]^{2+}$ ion to be more rigid, which is probably the reason ΔS° is slightly negative.

We can use Equation 19.20, $\Delta G^\circ = -RT \ln K$, to calculate the equilibrium constant of the reaction at 27 °C. The result, $K = 3.1 \times 10^7$, tells us that the equilibrium lies far to the right, favoring replacement of H_2O by NH_3. For this equilibrium, therefore, the enthalpy change, $\Delta H^\circ = -46$ kJ, is large enough and negative enough to overcome the entropy change, $\Delta S^\circ = -8.4$ J/K.

Now let's use a single bidentate ethylenediamine (en) ligand in our substitution reaction:

$$[Cu(H_2O)_4]^{2+}(aq) + \text{en}(aq) \rightleftharpoons [Cu(H_2O)_2(\text{en})]^{2+}(aq) + 2\,H_2O(l)$$

$$\Delta H^\circ = -54\text{ kJ};\quad \Delta S^\circ = +23\text{ J/K};\quad \Delta G^\circ = -61\text{ kJ}$$

The en ligand binds slightly more strongly to the Cu^{2+} ion than two NH_3 ligands, so the enthalpy change here (−54 kJ) is slightly more negative than for $[Cu(H_2O)_2(NH_3)_2]^{2+}$(−46 kJ). There is a big difference in the entropy change, however: ΔS° is $-8.4\ \text{J/K}$ for the NH_3 reaction but $+23\ \text{J/K}$ for the en reaction. We can explain the positive ΔS° value using concepts discussed in Section 19.3. Because a single en ligand occupies two coordination sites, two molecules of H_2O are released when one en ligand bonds. Thus, there are three product molecules in the reaction but only two reactant molecules. The greater number of product molecules leads to the positive entropy change for the equilibrium.

The slightly more negative value of ΔH° for the en reaction (-54 kJ versus -46 kJ) coupled with the positive entropy change leads to a much more negative value of ΔG° (-61 kJ for en, -43 kJ for NH_3) and thus a larger equilibrium constant: $K = 4.2 \times 10^{10}$.

We can combine our two equations using Hess's law (Section 5.6) to calculate the enthalpy, entropy, and free-energy changes that occur for en to replace ammonia as ligands on Cu(II):

$$[Cu(H_2O)_2(NH_3)_2]^{2+}(aq) + en(aq) \rightleftharpoons [Cu(H_2O)_2(en)]^{2+}(aq) + 2\,NH_3(aq)$$

$$\Delta H^\circ = (-54\ \text{kJ}) - (-46\ \text{kJ}) = -8\ \text{kJ}$$
$$\Delta S^\circ = (+23\ \text{J/K}) - (-8.4\ \text{J/K}) = +31\ \text{J/K}$$
$$\Delta G^\circ = (-61\ \text{kJ}) - (-43\ \text{kJ}) = -18\ \text{kJ}$$

Notice that at 27 °C, the entropic contribution ($-T\Delta S^\circ$) to the free-energy change, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ (Equation 19.12), is negative and greater in magnitude than the enthalpic contribution (ΔH°). The equilibrium constant for the NH_3–en reaction, 1.4×10^3, shows that the replacement of NH_3 by en is thermodynamically favorable.

The chelate effect is important in biochemistry and molecular biology. The additional thermodynamic stabilization provided by entropy effects helps stabilize biological metal–chelate complexes, such as porphyrins, and can allow changes in the oxidation state of the metal ion while retaining the structural integrity of the complex.

Related Exercises: 23.31, 23.32, 23.96, 23.98

The **chlorophylls**, which are porphyrins that contain Mg(II) (Figure 23.13), are the key components in the conversion of solar energy into forms that can be used by living organisms. This process, called **photosynthesis**, occurs in the leaves of green plants:

$$6\,CO_2(g) + 6\,H_2O(l) \longrightarrow C_6H_{12}O_6(aq) + 6\,O_2(g) \qquad [23.6]$$

The formation of 1 mol of glucose, $C_6H_{12}O_6$, requires the absorption of 48 mol of photons from sunlight or other sources of light. Chlorophyll-containing pigments in the leaves of plants absorb the photons. Figure 23.13 shows that the chlorophyll molecule has a series of alternating, or *conjugated*, double bonds in the ring surrounding the metal ion. This system of conjugated double bonds makes it possible for chlorophyll to absorb light strongly in the visible region of the spectrum. As ▶ Figure 23.16 shows, chlorophyll is green because it absorbs red light (maximum absorption at 655 nm) and blue light (maximum absorption at 430 nm) and transmits green light.

Photosynthesis is nature's solar energy–conversion machine, and thus all living systems on Earth depend on photosynthesis for continued existence.

Give It Some Thought

What property of the porphine ligand makes it possible for chlorophyll to play a role in plant photosynthesis?

Chemistry and Life

The Battle for Iron In Living Systems

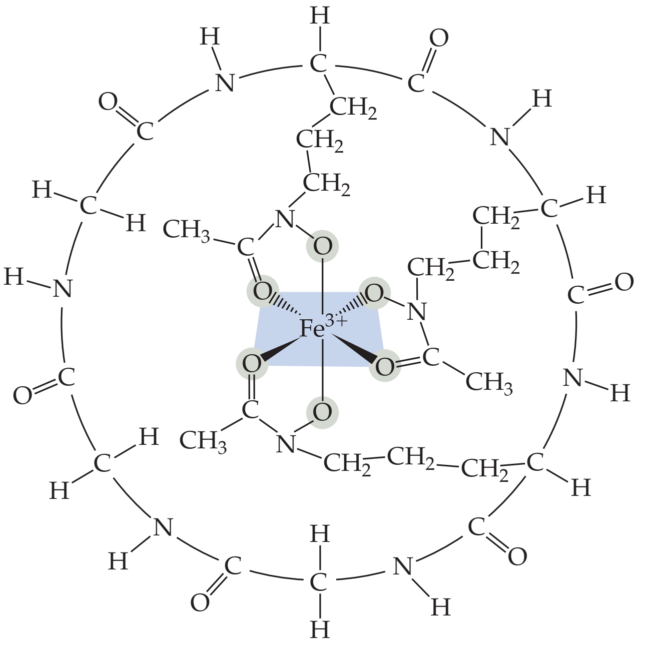
Because living systems have difficulty assimilating enough iron to satisfy their nutritional needs, iron-deficiency anemia is a common problem in humans. Chlorosis, an iron deficiency in plants that makes leaves turn yellow, is also commonplace.

Living systems have difficulty assimilating iron because most iron compounds found in nature are not very soluble in water. Microorganisms have adapted to this problem by secreting an iron-binding compound, called a *siderophore*, that forms an extremely stable water-soluble complex with iron(III). One such complex is *ferrichrome* (Figure 23.17). The iron-binding strength of a siderophore is so great that it can extract iron from iron oxides.

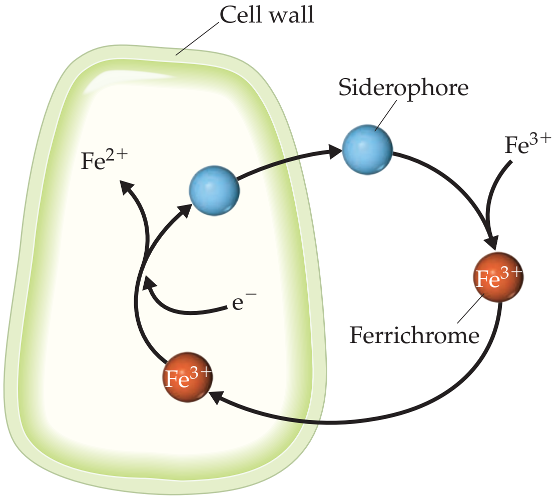
When ferrichrome enters a living cell, the iron it carries is removed through an enzyme-catalyzed reaction that reduces the strongly bonding iron(III) to iron(II), which is only weakly complexed by the siderophore (Figure 23.18). Microorganisms thus acquire iron by excreting a siderophore into their immediate environment and then taking the resulting iron complex into the cell.

In humans, iron is assimilated from food in the intestine. A protein called *transferrin* binds iron and transports it across the intestinal wall to distribute it to other tissues in the body. The normal adult body contains about 4 g of iron. At any one time, about 3 g of this iron is in the blood, mostly in the form of hemoglobin. Most of the remainder is carried by transferrin.

A bacterium that infects the blood requires a source of iron if it is to grow and reproduce. The bacterium excretes a siderophore into the



▲ **Figure 23.17** **Ferrichrome.**



▲ **Figure 23.18** **The iron-transport system of a bacterial cell.**

blood to compete with transferrin for iron. The equilibrium constants for forming the iron complex are about the same for transferrin and siderophores. The more iron available to the bacterium, the more rapidly it can reproduce and thus the more harm it can do.

Several years ago, New Zealand clinics regularly gave iron supplements to infants soon after birth. However, the incidence of certain bacterial infections was eight times higher in treated than in untreated infants. Presumably, the presence of more iron in the blood than absolutely necessary makes it easier for bacteria to obtain the iron needed for growth and reproduction.

In the United States, it is common medical practice to supplement infant formula with iron sometime during the first year of life. However, iron supplements are not necessary for infants who breast-feed because breast milk contains two specialized proteins, lactoferrin and transferrin, which provide sufficient iron while denying its availability to bacteria. Even for infants fed with infant formulas, supplementing with iron during the first several months of life may be ill-advised.

For bacteria to continue to multiply in the blood, they must synthesize new supplies of siderophores. Synthesis of siderophores in bacteria slows, however, as the temperature is increased above the normal body temperature of 37 °C and stops completely at 40 °C. This suggests that fever in the presence of an invading microbe is a mechanism used by the body to deprive bacteria of iron.

Related Exercise: 23.74

23.4 | Nomenclature and Isomerism in Coordination Chemistry

When complexes were first discovered, they were named after the chemist who originally prepared them. A few of these names persist, as, for example, with the dark red substance $NH_4[Cr(NH_3)_2(NCS)_4]$, which is still known as Reinecke's salt. Once the structures of complexes were more fully understood, it became possible to name them in a more systematic manner. Let's use two substances to illustrate how coordination compounds are named:

$$[Co(NH_3)_5Cl]Cl_2 \qquad \overbrace{\underbrace{\text{Pentaammine}}_{\text{5 NH}_3\text{ ligands}}\underbrace{\text{chloro}}_{\text{Cl}^-\text{ ligand}}\underbrace{\text{cobalt(III)}}_{\text{Cobalt in +3 oxidation state}}}^{\text{Cation}} \qquad \overbrace{\text{Chloride}}^{\text{Anion}}$$

$$Na_2[MoOCl_4] \qquad \overbrace{\text{Sodium}}^{\text{Cation}} \qquad \overbrace{\underbrace{\text{Tetrachloro}}_{\text{4 Cl}^-\text{ ligands}}\underbrace{\text{oxo}}_{\text{Oxide, O}^{2-}\text{ ligand}}\underbrace{\text{molybdate(IV)}}_{\text{Molybdenum in +4 oxidation state}}}^{\text{Anion}}$$

1. **In naming complexes that are salts, the name of the cation is given before the name of the anion**. Thus, in $[Co(NH_3)_5Cl]Cl_2$ we name the $[Co(NH_3)_5Cl]^{2+}$ cation and then the Cl^-.
2. **In naming complex ions or molecules, the ligands are named before the metal. Ligands are listed in alphabetical order, regardless of their charges. Prefixes that give the number of ligands are not considered part of the ligand name in determining alphabetical order**. Thus, the $[Co(NH_3)_5Cl]^{2+}$ ion is pentaamminechlorocobalt(III). (Be careful to note, however, that the metal is written first in the chemical formula.)
3. **The names of anionic ligands end in the letter *o*, but electrically neutral ligands ordinarily bear the name of the molecules** (▲ Table 23.5). Special names are used for H_2O (aqua), NH_3 (ammine), and CO (carbonyl). For example, $[Fe(CN)_2(NH_3)_2(H_2O)_2]^+$ is the diamminediaquadicyanoiron(III) ion.
4. **Greek prefixes (*di-*, *tri-*, *tetra-*, *penta-*, *hexa-*) are used to indicate the number of each kind of ligand when more than one is present. If the ligand contains a Greek prefix (for example, *ethylenediamine*) or is polydentate, the alternate prefixes *bis-*, *tris-*, *tetrakis-*, *pentakis-*, and *hexakis-* are used and the ligand name is placed in parentheses**. For example, the name for $[Co(en)_3]Br_3$ is tris(ethylenediamine)-cobalt(III) bromide.
5. **If the complex is an anion, its name ends in *-ate***. The compound $K_4[Fe(CN)_6]$ is potassium hexacyanoferrate(II), for example, and the ion $[CoCl_4]^{2-}$ is tetrachlorocobaltate(II) ion.
6. **The oxidation number of the metal is given in parentheses in Roman numerals following the name of the metal**.

Three examples for applying these rules are

$[Ni(NH_3)_6]Br_2$	Hexaamminenickel(II) bromide
$[Co(en)_2(H_2O)(CN)]Cl_2$	Aquacyanobis(ethylenediamine)cobalt(III) chloride
$Na_2[MoOCl_4]$	Sodium tetrachlorooxomolybdate(IV)

Table 23.5 Some Common Ligands and Their Names

Ligand	Name in Complexes	Ligand	Name in Complexes
Azide, N_3^-	Azido	Oxalate, $C_2O_4^{2-}$	Oxalato
Bromide, Br^-	Bromo	Oxide, O^{2-}	Oxo
Chloride, Cl^-	Chloro	Ammonia, NH_3	Ammine
Cyanide, CN^-	Cyano	Carbon monoxide, CO	Carbonyl
Fluoride, F^-	Fluoro	Ethylenediamine, en	Ethylenediamine
Hydroxide, OH^-	Hydroxo	Pyridine, C_5H_5N	Pyridine
Carbonate, CO_3^{2-}	Carbonato	Water, H_2O	Aqua

SAMPLE EXERCISE 23.3 Naming Coordination Compounds

Name the compounds **(a)** $[Cr(H_2O)_4Cl_2]Cl$, **(b)** $K_4[Ni(CN)_4]$.

SOLUTION

Analyze We are given the chemical formulas for two coordination compounds and assigned the task of naming them.

Plan To name the complexes, we need to determine the ligands in the complexes, the names of the ligands, and the oxidation state of the metal ion. We then put the information together following the rules listed in the text.

Solve

(a) The ligands are four water molecules—tetraaqua—and two chloride ions—dichloro. By assigning all the oxidation numbers we know for this molecule, we see that the oxidation number of Cr is +3:

$$+3 + 4(0) + 2(-1) + (-1) = 0$$

$$[Cr(H_2O)_4Cl_2]Cl$$

Thus, we have chromium(III). Finally, the anion is chloride. The name of the compound is tetraaquadichlorochromium(III) chloride.

(b) The complex has four cyanide ion ligands, CN^-, which means tetracyano, and the oxidation state of the nickel is zero:

$$\begin{array}{c} 4(+1) + 0 + 4(-1) = 0 \\ \downarrow \quad \swarrow \quad \swarrow \\ K_4[Ni(CN)_4] \end{array}$$

Because the complex is an anion, the metal is indicated as nickelate(0). Putting these parts together and naming the cation first, we have potassium tetracyanonickelate(0).

Practice Exercise 1

What is the name of the compound $[Rh(NH_3)_4Cl_2]Cl$? **(a)** Rhodium(III) tetraamminedichloro chloride, **(b)** Tetraammoniadichlororhodium(III) chloride, **(c)** Tetraamminedichlororhodium(III) chloride, **(d)** Tetraamminetrichlororhodium(III), **(e)** Tetraamminedichlororhodium(II) chloride.

Practice Exercise 2

Name the compounds **(a)** $[Mo(NH_3)_3Br_3]NO_3$, **(b)** $(NH_4)_2[CuBr_4]$. **(c)** Write the formula for sodium diaquabis(oxalato)ruthenate(III).

Isomerism

When two or more compounds have the same composition but a different arrangement of atoms, we call them **isomers**. (Section 2.9) Here we consider two main kinds of isomers in coordination compounds: **structural isomers** (which have different bonds) and **stereoisomers** (which have the same bonds but different ways in which the ligands occupy the space around the metal center). Each of these classes also has subclasses, as shown in ▼ Figure 23.19.

Structural Isomerism

Many types of structural isomerism are known in coordination chemistry, including the two named in Figure 23.19: linkage isomerism and coordination-sphere isomerism. **Linkage isomerism** is a relatively rare but interesting type that arises when a particular ligand is capable of coordinating to a metal in two ways. The nitrite ion, NO_2^-, for example, can coordinate to a metal ion through either its nitrogen or one of its oxygens

▲ Figure 23.19 Forms of isomerism in coordination compounds.

(▶ Figure 23.20). When it coordinates through the nitrogen atom, the NO_2^- ligand is called *nitro*; when it coordinates through the oxygen atom, it is called *nitrito* and is generally written ONO^-. The isomers shown in Figure 23.20 have different properties. The nitro isomer is yellow, for example, whereas the nitrito isomer is red.

Another ligand capable of coordinating through either of two donor atoms is thiocyanate, SCN^-, whose potential donor atoms are N and S.

Give It Some Thought

Can the ammonia ligand engage in linkage isomerism? Explain.

Coordination-sphere isomers are isomers that differ in which species in the complex are ligands and which are outside the coordination sphere in the solid. For example, three isomers have the formula $CrCl_3(H_2O)_6$. When the ligands are six H_2O and the chloride ions are in the crystal lattice (as counterions), we have the violet compound $[Cr(H_2O)_6]Cl_3$. When the ligands are five H_2O and one Cl^-, with the sixth H_2O and the two Cl^- out in the lattice, we have the green compound $[Cr(H_2O)_5Cl]Cl_2 \cdot H_2O$. The third isomer, $[Cr(H_2O)_4Cl_2]Cl \cdot 2\,H_2O$, is also a green compound. In the two green compounds, either one or two water molecules have been displaced from the coordination sphere by chloride ions. The displaced H_2O molecules occupy a site in the crystal lattice.

GO FIGURE

Nitrito isomer
Bonding via ligand O atom

▲ Figure 23.20 **Linkage isomerism.**

Stereoisomerism

Stereoisomers have the same chemical bonds but different spatial arrangements. In the square-planar complex $[Pt(NH_3)_2Cl_2]$, for example, the chloro ligands can be either adjacent to or opposite each other (▼ Figure 23.21). (We saw an earlier example of this type of isomerism in the cobalt complex of Figure 23.8, and we will return to that complex in a moment.) This form of stereoisomerism, in which the arrangement of the atoms is different but the same bonds are present, is called **geometric isomerism**. The isomer on the left in

cis
Cl ligands adjacent to each other
NH_3 ligands adjacent to each other

trans
Cl ligands on opposite sides of central atom
NH_3 ligands on opposite sides of central atom

▲ Figure 23.21 **Geometric isomerism.**

Figure 23.21, with like ligands in adjacent positions, is the cis isomer, and the isomer on the right, with like ligands across from one another, is the trans isomer.

Geometric isomers generally have different physical properties and may also have markedly different chemical reactivities. For example, *cis*-$[Pt(NH_3)_2Cl_2]$, also called *cisplatin*, is effective in the treatment of testicular, ovarian, and certain other cancers, whereas the trans isomer is ineffective. This is because cisplatin forms a chelate with two nitrogens of DNA, displacing the chloride ligands. The chloride ligands of the trans isomer are too far apart to form the N-Pt-N chelate with the nitrogen donors in DNA.

Geometric isomerism is also possible in octahedral complexes when two or more different ligands are present, as in the cis and trans tetraamminedichlorocobalt(III) ion in Figure 23.8. Because all the corners of a tetrahedron are adjacent to one another, cis–trans isomerism is not observed in tetrahedral complexes.

SAMPLE EXERCISE 23.4 Determining the Number of Geometric Isomers

The Lewis structure $:C\equiv O:$ indicates that the CO molecule has two lone pairs of electrons. When CO binds to a transition-metal atom, it nearly always does so by using the C lone pair. How many geometric isomers are there for tetracarbonyldichloroiron(II)?

SOLUTION

Analyze We are given the name of a complex containing only monodentate ligands, and we must determine the number of isomers the complex can form.

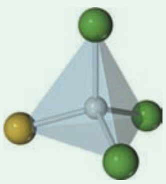
Plan We can count the number of ligands to determine the coordination number of the Fe and then use the coordination number to predict the geometry. We can then either make a series of drawings with ligands in different positions to determine the number of isomers or deduce the number of isomers by analogy to cases we have discussed.

Solve The name indicates that the complex has four carbonyl (CO) ligands and two chloro (Cl^-) ligands, so its formula is $Fe(CO)_4Cl_2$. The complex therefore has a coordination number of 6, and we can assume an octahedral geometry. Like $[Co(NH_3)_4Cl_2]^+$ (Figure 23.8), it has four ligands of one type and two of another. Consequently, there are two isomers possible: one with the Cl^- ligands across the metal from each other, *trans*-$[Fe(CO)_4Cl_2]$, and one with the Cl^- ligands adjacent to each other, *cis*-$[Fe(CO)_4Cl_2]$.

Comment It is easy to overestimate the number of geometric isomers. Sometimes different orientations of a single isomer are incorrectly thought to be different isomers. If two structures can be rotated so that they are equivalent, they are not isomers of each other. The problem of identifying isomers is compounded by the difficulty we often have in visualizing three-dimensional molecules from their two-dimensional representations. It is sometimes easier to determine the number of isomers if we use three-dimensional models.

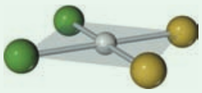
Practice Exercise 1

Which of the following molecules does not have a geometric isomer?



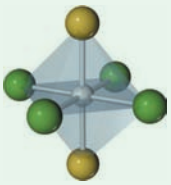
$[MX_3Y]$

(a)



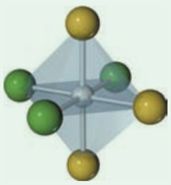
$[MX_2Y_2]$

(b)



$[MX_4Y_2]$

(c)



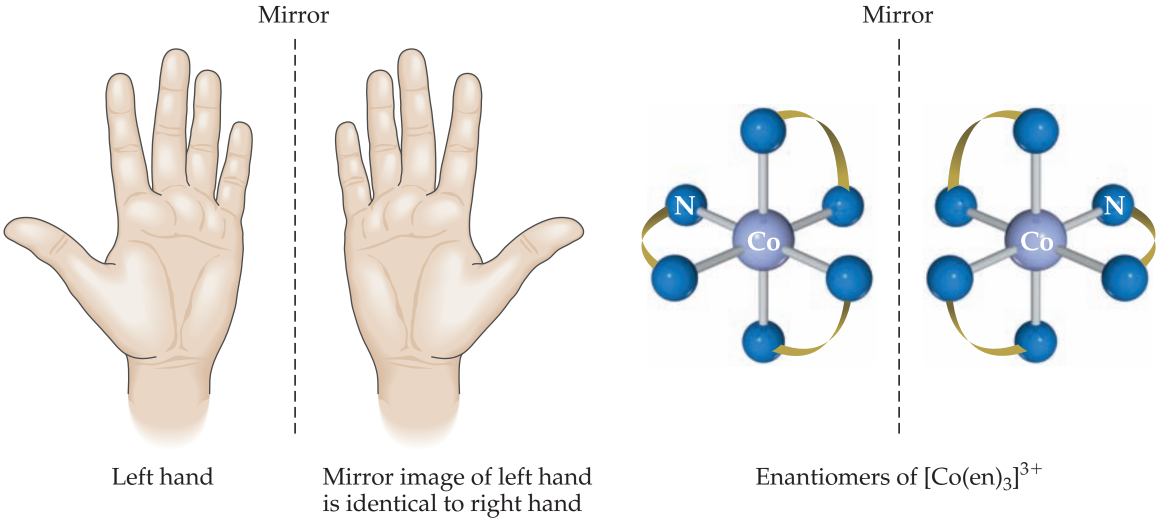
$[MX_3Y_3]$

(d)

Practice Exercise 2

How many isomers exist for the square-planar molecule $[Pt(NH_3)_2ClBr]$?

The second type of stereoisomerism listed in Figure 23.19 is **optical isomerism**. Optical isomers, called **enantiomers**, are mirror images that cannot be superimposed on each other. They bear the same resemblance to each other that your left hand bears to your right hand. If you look at your left hand in a mirror, the image is identical to your right hand (▶ Figure 23.22). No matter how hard you try, however, you cannot



Mirror
Mirror

▲ **Figure 23.22** **Optical isomerism.**

superimpose your two hands on each other. An example of a complex that exhibits this type of isomerism is the $[Co(en)_3]^{3+}$ ion. Figure 23.22 shows the two enantiomers of this complex and their mirror-image relationship. Just as there is no way that we can twist or turn our right hand to make it look identical to our left, so also there is no way to rotate one of these enantiomers to make it identical to the other. Molecules or ions that are not superimposable on their mirror image are said to be **chiral** (pronounced KY-rul).

SAMPLE EXERCISE 23.5 Predicting Whether a Complex Has Optical Isomers

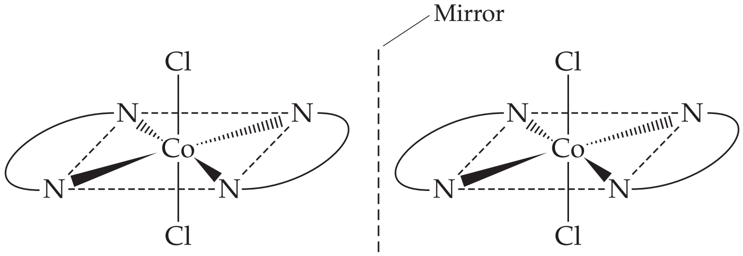
Does either *cis*-$[Co(en)_2Cl_2]^+$ or *trans*-$[Co(en)_2Cl_2]^-$ have optical isomers?

SOLUTION

Analyze We are given the chemical formula for two geometric isomers and asked to determine whether either one has optical isomers. Because en is a bidentate ligand, we know that both complexes are octahedral and both have coordination number 6.

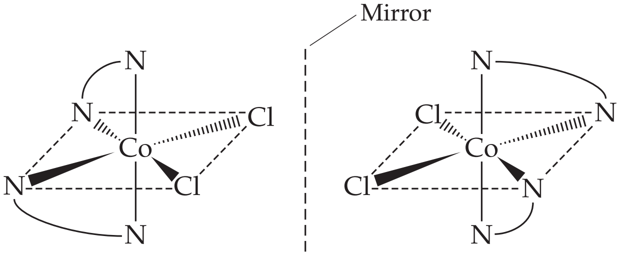
Plan We need to sketch the structures of the cis and trans isomers and their mirror images. We can draw the en ligand as two N atoms connected by an arc. If the mirror image cannot be superimposed on the original structure, the complex and its mirror image are optical isomers.

Solve The trans isomer of $[Co(en)_2Cl_2]^+$ and its mirror image are:



Notice that the mirror image of the isomer is identical to the original. Consequently *trans*-$[Co(en)_2Cl_2]^+$ does not exhibit optical isomerism.

The mirror image of the cis isomer cannot be superimposed on the original:



Thus, the two cis structures are optical isomers (enantiomers). We say that *cis*-$[Co(en)_2Cl_2]^+$ is a chiral complex.

Practice Exercise 1

Which of the following complexes has optical isomers? **(a)** Tetrahedral $[CdBr_2Cl_2]^{2-}$, **(b)** Octahedral $[CoCl_4(en)]^{2-}$, **(c)** Octahedral $[Co(NH_3)_4Cl_2]^{2+}$, **(d)** Tetrahedral $[Co(NH_3)BrClI]^-$.

Practice Exercise 2

Does the square-planar complex ion $[Pt(NH_3)(N_3)ClBr]^-$ have optical isomers? Explain your answer.

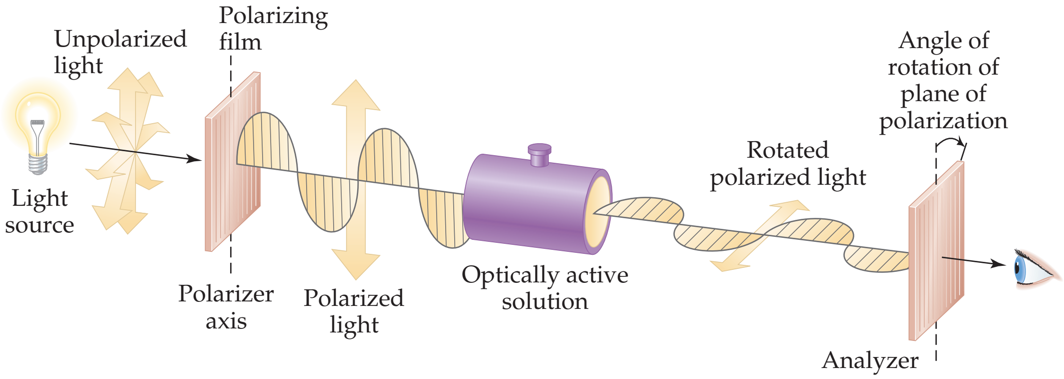
The properties of two optical isomers differ only if the isomers are in a chiral environment—that is, an environment in which there is a sense of right- and left-handedness. A chiral enzyme, for example, might catalyze the reaction of one optical isomer but not the other. Consequently, one optical isomer may produce a specific physiological effect in the body, with its mirror image producing either a different effect or none at all. Chiral reactions are also extremely important in the synthesis of pharmaceuticals and other industrially important chemicals.

Optical isomers are usually distinguished from each other by their interaction with plane-polarized light. If light is polarized—for example, by being passed through a sheet of polarizing film—the electric-field vector of the light is confined to a single plane (▼ Figure 23.23). If the polarized light is then passed through a solution containing one optical isomer, the plane of polarization is rotated either to the right or to the left. The isomer that rotates the plane of polarization to the right is **dextrorotatory**; it is the dextro, or *d*, isomer (Latin *dexter*, "right"). Its mirror image rotates the plane of polarization to the left; it is **levorotatory** and is the levo, or *l*, isomer (Latin *laevus*, "left"). The $[Co(en)_3]^{3+}$ isomer on the right in Figure 23.22 is found experimentally to be the *l* isomer of this ion. Its mirror image is the *d* isomer. Because of their effect on plane-polarized light, chiral molecules are said to be **optically active**.

Give It Some Thought

What is the similarity and what is the difference between the *d* and *l* isomers of a compound?

When a substance with optical isomers is prepared in the laboratory, the chemical environment during the synthesis is not usually chiral. Consequently, equal amounts of the two isomers are obtained, and the mixture is said to be **racemic**. A racemic mixture does not rotate polarized light because the rotatory effects of the two isomers cancel each other.



▲ Figure 23.23 **Using polarized light to detect optical activity.**

23.5 | Color and Magnetism in Coordination Chemistry

Studies of the colors and magnetic properties of transition-metal complexes have played an important role in the development of modern models for metal–ligand bonding. We discussed the various types of magnetic behavior of the transition metals in Section 23.1, and we discussed the interaction of radiant energy with matter in Section 6.3. Let's briefly examine the significance of these two properties for transition-metal complexes before we develop a model for metal–ligand bonding.

Color

In Figure 23.4, we saw the diverse range of colors seen in salts of transition-metal ions and their aqueous solutions. In general, the color of a complex depends on the identity of the metal ion, on its oxidation state, and on the ligands bound to it. ▼ **Figure 23.24**, for instance, shows how the pale blue color characteristic of $[Cu(H_2O)_4]^{2+}$ changes to deep blue-violet as NH_3 ligands replace the H_2O ligands to form $[Cu(NH_3)_4]^{2+}$.

For a substance to have color we can see, it must absorb some portion of the spectrum of visible light. ∞ (Section 6.1) Absorption happens, however, only if the energy needed to move an electron in the substance from its ground state to an excited state corresponds to the energy of some portion of the visible spectrum. ∞ (Section 6.3) Thus, the particular energies of radiation a substance absorbs dictate the color we see for the substance.

When an object absorbs some portion of the visible spectrum, the color we perceive is the sum of the unabsorbed portions, which are either reflected or transmitted by the object and strike our eyes. (Opaque objects *reflect* light, and transparent ones *transmit* it.) If an object absorbs all wavelengths of visible light, none reaches our eyes and the object appears black. If it absorbs no visible light, it is white if opaque or colorless if transparent. If it absorbs all but orange light, the orange light is what reaches our eye and therefore is the color we see.

▲ **Figure 23.25 Two ways of perceiving the color orange.** An object appears orange either when it reflects orange light to the eye (left), or when it transmits to the eye all colors except blue, the complement of orange (middle). Complementary colors lie opposite to each other on an artist's color wheel (right).

An interesting phenomenon of vision is that we also perceive an orange color when an object absorbs only the blue portion of the visible spectrum and all the other colors strike our eyes. This is because orange and blue are **complementary colors**, which means that the removal of blue from white light makes the light look orange (and the removal of orange makes the light look blue).

Complementary colors can be determined with an artist's color wheel, which shows complementary colors on opposite sides (▲ Figure 23.25).

The amount of light absorbed by a sample as a function of wavelength is known as the sample's **absorption spectrum**. The visible absorption spectrum of a transparent sample can be determined using a spectrometer, as described in the "A Closer Look" box on page 582. The absorption spectrum of the ion $[\mathrm{Ti(H_2O)_6}]^{3+}$ is shown in ▶ Figure 23.26. The absorption maximum is at 500 nm, but the graph shows that much of the yellow, green, and blue light is also absorbed. Because the sample absorbs all of these colors, what we see is the unabsorbed red and violet light, which we perceive as purple (the color purple is classified as a tertiary color located between red and violet on an artists color wheel).

SAMPLE EXERCISE 23.6 Relating Color Absorbed to Color Observed

The complex ion *trans*-$[\mathrm{Co(NH_3)_4Cl_2}]^+$ absorbs light primarily in the red region of the visible spectrum (the most intense absorption is at 680 nm). What is the color of the complex ion?

SOLUTION

Analyze We need to relate the color absorbed by a complex (red) to the color observed for the complex.

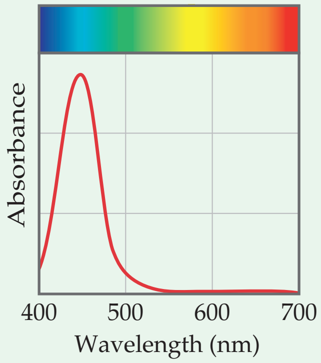
Plan For an object that absorbs only one color from the visible spectrum, the color we see is complementary to the color absorbed. We can use the color wheel of Figure 23.25 to determine the complementary color.

Solve From Figure 23.25, we see that green is complementary to red, so the complex appears green.

Comment As noted in Section 23.2, this green complex was one of those that helped Werner establish his theory of coordination (Table 23.3). The other geometric isomer of this complex, *cis*-$[\mathrm{Co(NH_3)_4Cl_2}]^+$, absorbs yellow light and therefore appears violet.

Practice Exercise 1

A solution containing a certain transition-metal complex ion has the absorption spectrum shown here.



What color would you expect a solution containing this ion to be? **(a)** violet, **(b)** blue, **(c)** green, **(d)** orange, **(e)** red.

Practice Exercise 2

A certain transition-metal complex ion absorbs at 695 nm. Which color is this ion most likely to be—blue, yellow, green, or red?

Magnetism of Coordination Compounds

Many transition-metal complexes exhibit paramagnetism, as described in Sections 9.8 and 23.1. In such compounds the metal ions possess some number of unpaired electrons. It is possible to experimentally determine the number of unpaired electrons per metal ion from the measured degree of paramagnetism, and experiments reveal some interesting comparisons.

Compounds of the complex ion $[Co(CN)_6]^{3-}$ have no unpaired electrons, for example, but compounds of the $[CoF_6]^{3-}$ ion have four unpaired electrons per metal ion. Both complexes contain Co(III) with a $3d^6$ electron configuration. (Section 7.4) Clearly, there is a major difference in the ways in which the electrons are arranged in these two cases. Any successful bonding theory must explain this difference, and we present such a theory in the next section.

Give It Some Thought

What is the electron configuration for **(a)** the Co atom and **(b)** the Co^{3+} ion? How many unpaired electrons does each possess? (See Section 7.4 to review electron configurations of ions.)

23.6 | Crystal-field Theory

Scientists have long recognized that many of the magnetic properties and colors of transition-metal complexes are related to the presence of *d* electrons in the metal cation. In this section, we consider a model for bonding in transition-metal complexes, **crystal-field theory**, that accounts for many of the observed properties of these substances.* Because the predictions of crystal-field theory are essentially the same as those obtained with more advanced molecular-orbital theories, crystal-field theory is an excellent place to start in considering the electronic structure of coordination compounds.

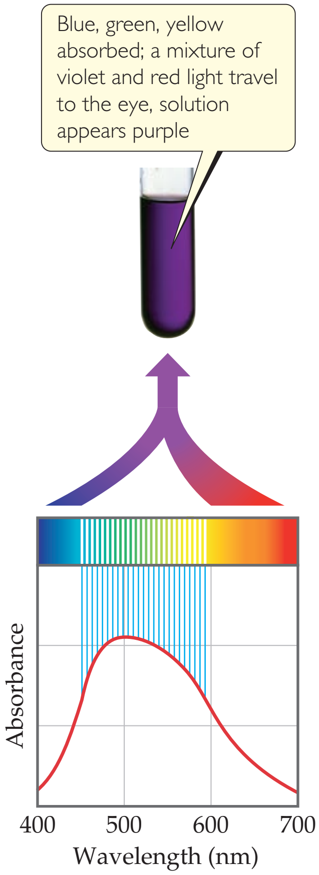
The attraction of a ligand to a metal ion is essentially a Lewis acid–base interaction in which the base—that is, the ligand—donates a pair of electrons to an empty orbital on the metal ion (▶ Figure 23.27). Much of the attractive interaction between the metal ion and the ligands is due, however, to the electrostatic forces between the positive charge on the metal ion and negative charges on the ligands. An ionic ligand, such as Cl^- or SCN^-, experiences the usual cation–anion attraction. When the ligand is a neutral molecule, as in the case of H_2O or NH_3, the negative ends of these polar molecules, which contain an unshared electron pair, are directed toward the metal ion. In this case, the attractive interaction is of the ion–dipole type. (Section 11.2) In either case, the ligands are attracted strongly toward the metal ion. Because of the metal–ligand electrostatic attraction, the energy of the complex is lower than the combined energy of the separated metal ion and ligands.

Although the metal ion is attracted to the ligand electrons, the metal ion's *d* electrons are repulsed by the ligands. Let's examine this effect more closely, specifically the case in which the ligands form an octahedral array around a metal ion that has coordination number 6.

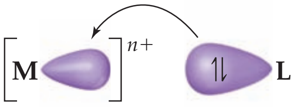
In crystal-field theory, we consider the ligands to be negative points of charge that repel the negatively charged electrons in the *d* orbitals of the metal ion. The energy diagram in **Figure 23.28** shows how these ligand point charges affect the energies of the *d* orbitals. First we imagine the complex as having all the ligand point charges uniformly distributed on the surface of a sphere centered on the metal ion. The *average* energy of the metal ion's *d* orbitals is raised by the presence of this uniformly charged sphere. Hence, the energies of all five *d* orbitals are raised by the same amount.

GO FIGURE

How would this absorbance spectrum change if you decreased the concentration of the $[Ti(H_2O)_6]^{3+}$ in solution?



▲ Figure 23.26 **The color of $[Ti(H_2O)_6]^{3+}$** A solution containing the $[Ti(H_2O)_6]^{3+}$ ion appears purple because, as its visible absorption spectrum shows, the solution does not absorb light from the violet and red ends of the spectrum. That unabsorbed light is what reaches our eyes.



▲ Figure 23.27 **Metal–ligand bond formation.** The ligand acts as a Lewis base by donating its nonbonding electron pair to an empty orbital on the metal ion. The bond that results is strongly polar with some covalent character.

---

*The name *crystal field* arose because the theory was first developed to explain the properties of solid crystalline materials. The theory applies equally well to complexes in solution, however.

▲ **Figure 23.28** **Energies of *d* orbitals in a free metal ion, a spherically symmetric crystal field, and an octahedral crystal field.**

This energy picture is only a first approximation, however, because the ligands are not distributed uniformly on a spherical surface and, therefore, do not approach the metal ion equally from every direction. Instead, we envision the six ligands approaching along *x*-, *y*-, and *z*-axes, as shown on the right in Figure 23.28. This arrangement of ligands is called an *octahedral crystal field*. Because the metal ion's *d* orbitals have different orientations and shapes, they do not all experience the same repulsion from the ligands and, therefore, do not all have the same energy under the influence of the octahedral crystal field. To see why, we must consider the shapes of the *d* orbitals and how their lobes are oriented relative to the ligands.

Figure 23.28 shows that the lobes of the d_{z^2} and $d_{x^2-y^2}$ orbitals are directed *along* the *x*-, *y*-, and *z*-axes and so point directly toward the ligand point charges. In the d_{xy}, d_{xz}, and d_{yz} orbitals, however, the lobes are directed *between* the axes and so do not point directly toward the charges. The result of this difference in orientation—$d_{x^2-y^2}$ and d_{z^2} lobes point directly toward the ligand charges; d_{xy}, d_{xz}, and d_{yz} lobes do not—is that the energy of the $d_{x^2-y^2}$ and d_{z^2} orbitals is higher than the energy of the d_{xy}, d_{xz}, and d_{yz} orbitals. This difference in energy is represented by the red boxes in the energy diagram of Figure 23.28.

It might seem like the energy of the $d_{x^2-y^2}$ orbital should be different from that of the d_{z^2} orbital because the $d_{x^2-y^2}$ has four lobes pointing at ligands and the d_{z^2} has only two lobes pointing at ligands. However, the d_{z^2} orbital does have electron density in the *xy* plane, represented by the ring encircling the point where the two lobes meet. More advanced calculations show that two orbitals do indeed have the same energy in the presence of the octahedral crystal field.

Because their lobes point directly at the negative ligand charges, electrons in the metal ion's d_{z^2} and $d_{x^2-y^2}$ orbitals experience stronger repulsions than those in the d_{xy}, d_{xz}, and d_{yz} orbitals. As a result, the energy splitting shown in Figure 23.28 occurs. The three lower-energy *d* orbitals are called the t_2 set of orbitals, and the two higher-energy ones are called the *e* set.* The energy gap Δ between the two sets is often called the *crystal-field splitting energy*.

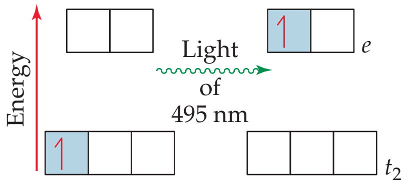
---

*The labels t_2 for the d_{xy}, d_{xz}, and d_{yz} orbitals and *e* for the d_{z^2} and $d_{x^2 2y^2}$ orbitals come from the application of a branch of mathematics called *group theory* to crystal-field theory. Group theory can be used to analyze the effects of symmetry on molecular properties.

Crystal-field theory helps us account for the colors observed in transition-metal complexes. The energy gap Δ between the *e* and t_2 sets of *d* orbitals is of the same order of magnitude as the energy of a photon of visible light. It is therefore possible for a transition-metal complex to absorb visible light that excites an electron from a lower-energy (t_2) *d* orbital into a higher-energy (*e*) *d* orbital. In $[Ti(H_2O)_6]^{3+}$, for example, the Ti(III) ion has an $[Ar]3d^1$ electron configuration. (Recall from Section 7.4 that when determining the electron configurations of transition-metal ions, we remove the *s* electrons first.) Ti(III) is thus called a d^1 *ion*. In the ground state of $[Ti(H_2O)_6]^{3+}$, the single 3*d* electron resides in an orbital in the t_2 set (▶ Figure 23.29). Absorption of 495-nm light excites this electron up to an orbital in the *e* set, generating the absorption spectrum shown in Figure 23.26. Because this transition involves exciting an electron from one set of *d* orbitals to the other, we call it a ***d-d* transition**. As noted earlier, the absorption of visible radiation that produces this *d-d* transition causes the $[Ti(H_2O)_6]^{3+}$ ion to appear purple.

GO FIGURE

How would you calculate the energy gap between the t_2 and *e* orbitals from this diagram?



▲ Figure 23.29 **The *d-d* transition in $[Ti(H_2O)_6]^{3+}$ is produced by the absorption of 495-nm light.**

Give It Some Thought

Why are compounds of Ti(IV) colorless?

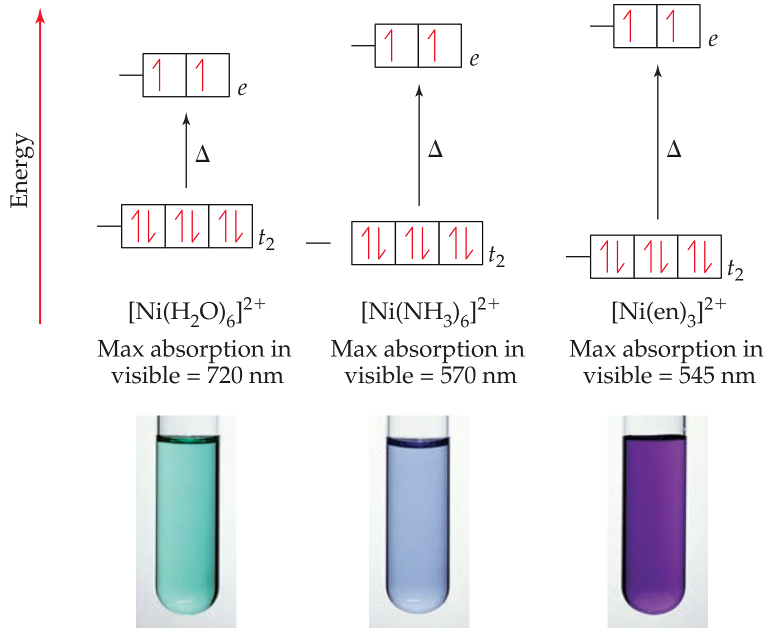
The magnitude of the crystal-field splitting energy and, consequently, the color of a complex depend on both the metal and the ligands. For example, we saw in Figure 23.4 that the color of $[M(H_2O)_6]^{2+}$ complexes changes from reddish-pink when the metal ion is Co^{2+}, to green for Ni^{2+}, to pale blue for Cu^{2+}. If we change the ligands in the $[Ni(H_2O)_6]^{2+}$ ion the color also changes. $[Ni(NH_3)_6]^{2+}$ has a blue-violet color, while $[Ni(en)_3]^{2+}$ is purple (▼ Figure 23.30). In a ranking called the **spectrochemical series**, ligands are arranged in order of their abilities to increase splitting energy, as in this abbreviated list:

$$\xrightarrow{\text{Increasing } \Delta}$$

$$Cl^- < F^- < H_2O < NH_3 < en < NO_2^-(\text{N-bonded}) < CN^-$$

GO FIGURE

If you were to use a ligand L that was a stronger field ligand than ethylenediamine, what color would you expect the $[NiL_6]^{2+}$ complex ion to have?



Energy
e
Δ
t2
[Ni(H2O)6]2+
Max absorption in visible = 720 nm
[Ni(NH3)6]2+
Max absorption in visible = 570 nm
[Ni(en)3]2+
Max absorption in visible = 545 nm

▲ Figure 23.30 **Effect of ligand on crystal-field splitting.** The greater the crystal-field strength of the ligand, the greater the energy gap Δ it causes between the t_2 and *e* sets of the metal ion's orbitals. This shifts the wavelength of the absorption maximum to shorter values.

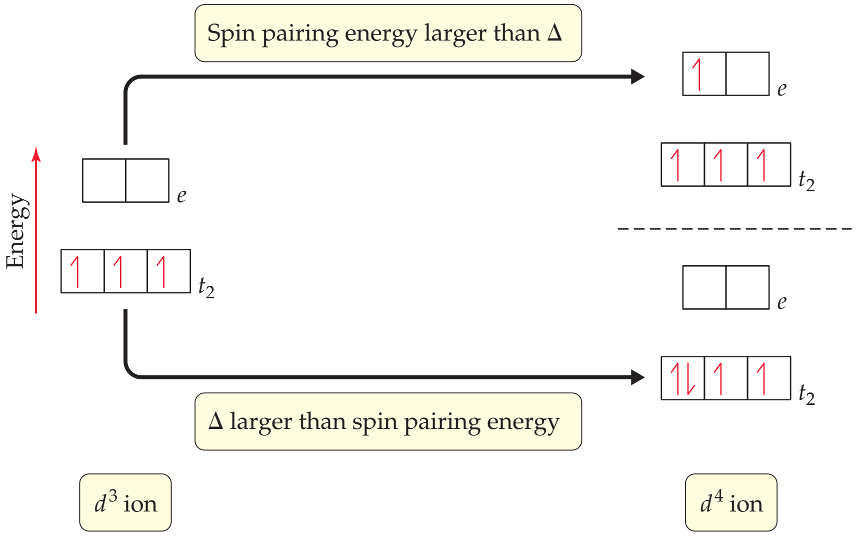
The magnitude of Δ increases by roughly a factor of 2 from the far left to the far right of the spectrochemical series. Ligands at the low-Δ end of the spectrochemical series are termed *weak-field ligands*; those at the high-Δ end are termed *strong-field ligands*.

Let's take a closer look at the colors and crystal field splitting as we vary the ligands for the series of Ni^{2+} complexes discussed above. Because the Ni atom has an $[Ar]3d^84s^2$ electron configuration, Ni^{2+} has the configuration $[Ar]3d^8$ and therefore is a d^8 ion. The t_2 set of orbitals holds six electrons, two in each orbital, while the last two electrons go into the *e* set of orbitals. Consistent with Hund's rule, each *e* orbital holds one electron and both electrons have the same spin. (Section 6.8)

As the ligand changes from H_2O to NH_3 to ethylenediamine the spectrochemical series tells us that the crystal field, Δ, exerted by the six ligands should increase. When there is more than one electron in the *d* orbitals, interactions between the electrons make the absorption spectra more complicated than the spectrum shown for $[Ti(H_2O)_6]^{3+}$ in Figure 23.26, which complicates the task of relating changes in Δ with color. With d^8 ions like Ni^{2+} three peaks are observed in the absorption spectra. Fortunately, for Ni^{2+} complexes we can simplify the analysis because only one of these three peaks falls in the visible region of the spectrum.* Because the energy separation Δ is increasing, the wavelength of the absorption peak should shift to a shorter wavelength. (Section 6.3) In the case of $[Ni(H_2O)_6]^{2+}$ the absorption peak in the visible part of the spectrum reaches a maximum near 720 nm, in the red region of the spectrum. So the complex ion takes the complementary color—green. For $[Ni(NH_3)_6]^{2+}$ the absorption peak reaches its maximum at 570 nm near the boundary between orange and yellow. The resulting color of the complex ion is a mixture of the complementary colors—blue and violet. Finally for $[Ni(en)_3]^{2+}$ the peak shifts to an even shorter wavelength, 540 nm, which lies near the boundary between green and yellow. The resulting color purple is a mixture of the complimentary colors red and violet.

Electron Configurations in Octahedral Complexes

Crystal-field theory helps us understand the magnetic properties and some important chemical properties of transition-metal ions. From Hund's rule, we expect electrons to always occupy the lowest-energy vacant orbitals first and to occupy a set of degenerate (same-energy) orbitals one at a time with their spins parallel. (Section 6.8) Thus, if we have a d^1, d^2, or d^3 octahedral complex, the electrons go into the lower-energy t_2 orbitals, with their spins parallel. When a fourth electron must be added, we have the two choices shown in ▼ **Figure 23.31**: The electron can either go into an *e* orbital, where



Spin pairing energy larger than Δ

d4 ion

▲ **Figure 23.31** **Two possibilities for adding a fourth electron to a d^3 octahedral complex.** Whether the fourth electron goes into a t_2 orbital or into an *e* orbital depends on the relative energies of the crystal-field splitting energy and the spin-pairing energy.

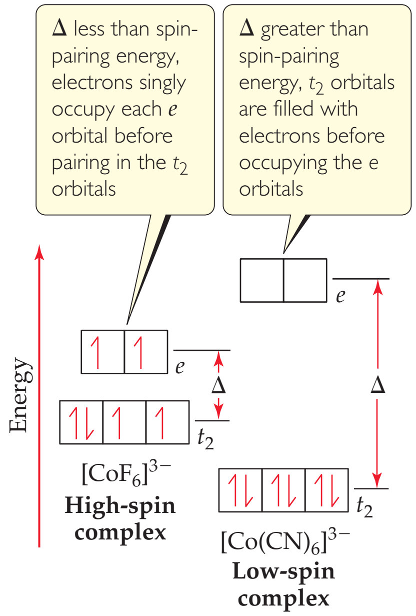
---

*The other two peaks fall in the infrared (IR) and ultraviolet (UV) regions of the spectrum. For $[Ni(H_2O)_6]^{2+}$ the IR peak is found at 1176 nm and the UV peak at 388 nm.

it will be the sole electron in the orbital, or become the second electron in a t_2 orbital. Because the energy difference between the t_2 and e sets is the splitting energy Δ, the energy cost of going into an e orbital rather than a t_2 orbital is also Δ. Thus, the goal of filling lowest-energy available orbitals first is met by putting the electron in a t_2 orbital.

There is a penalty for doing this, however, because the electron must now be paired with the electron already occupying the orbital. The difference between the energy required to pair an electron in an occupied orbital and the energy required to place that electron in an empty orbital is called the **spin-pairing energy**. The spin-pairing energy arises from the fact that the electrostatic repulsion between two electrons that share an orbital (and so must have opposite spins) is greater than the repulsion between two electrons that are in different orbitals and have parallel spins.

In coordination complexes, the nature of the ligands and the charge on the metal ion often play major roles in determining which of the two electron arrangements shown in Figure 23.31 is used. In $[CoF_6]^{3-}$ and $[Co(CN)_6]^{3-}$, both ligands have a 1− charge. The F^- ion, however, is on the low end of the spectrochemical series, so it is a weak-field ligand. The CN^- ion is on the high end and so is a strong-field ligand, which means it produces a larger energy gap Δ than the F^- ion. The splittings of the *d*-orbital energies in these two complexes are compared in ▶ Figure 23.32.



Δ less than spin-pairing energy, electrons singly occupy each e orbital before pairing in the t_2 orbitals
Δ greater than spin-pairing energy, t_2 orbitals are filled with electrons before occupying the e orbitals
Energy
e
Δ
t_2
$[CoF_6]^{3-}$
High-spin complex
e
Δ
t_2
$[Co(CN)_6]^{3-}$
Low-spin complex

▲ Figure 23.32 **High-spin and low-spin complexes.** The high-spin $[CoF_6]^{3-}$ ion has a weak-field ligand and so a small Δ value. The low-spin $[Co(CN)_6]^{3-}$ ion has a strong-field ligand and so a large Δ value.

Cobalt(III) has an $[Ar]3d^6$ electron configuration, so both complexes in Figure 23.32 are d^6 complexes. Let's imagine that we add these six electrons one at a time to the *d* orbitals of the $[CoF_6]^{3-}$ ion. The first three go into the t_2 orbitals with their spins parallel. The fourth electron could pair up in one of the t_2 orbitals. The F^- ion is a weak-field ligand, however, and so the energy gap Δ between the t_2 set and the *e* set is small. In this case, the more stable arrangement is the fourth electron in one of the *e* orbitals. By the same energy argument, the fifth electron goes into the other *e* orbital. With all five *d* orbitals containing one electron, the sixth must pair up, and the energy needed to place the sixth electron in a t_2 orbital is less than that needed to place it in an *e* orbital. We end up with four t_2 electrons and two *e* electrons.

Figure 23.32 shows that the crystal-field splitting energy Δ is much larger in the $[Co(CN)_6]^{3-}$ complex. In this case, the spin-pairing energy is smaller than Δ, so the lowest-energy arrangement is the six electrons paired in the t_2 orbitals.

The $[CoF_6]^{3-}$ complex is a **high-spin complex**; that is, the electrons are arranged so that they remain unpaired as much as possible. The $[Co(CN)_6]^{3-}$ ion is a **low-spin complex**; that is, the electrons are arranged so that they remain paired as much as possible while still following Hund's rule. These two electronic arrangements can be readily distinguished by measuring the magnetic properties of the complex. Experiments show that $[CoF_6]^{3-}$ has four unpaired electrons and $[Co(CN)_6]^{3-}$ has none. The absorption spectrum also shows peaks corresponding to the different values of Δ in these two complexes.

Give It Some Thought

In octahedral complexes, for which *d* electron configurations is it possible to have high-spin and low-spin arrangements with different numbers of unpaired electrons?

In the transition metal ions of periods 5 and 6 (which have 4*d* and 5*d* valence electrons), the *d* orbitals are larger than in the period 4 ions (which have only 3*d* electrons). Thus, ions from periods 5 and 6 interact more strongly with ligands, resulting in a larger crystal-field splitting. Consequently, metal ions in periods 5 and 6 are invariably low spin in an octahedral crystal field.

SAMPLE EXERCISE 23.7 The Spectrochemical Series, Crystal Field Splitting, Color, and Magnetism

The compound hexaamminecobalt(III) chloride is diamagnetic and orange in color with a single absorption peak in its visible absorption spectrum. **(a)** What is the electron configuration of the cobalt(III) ion? **(b)** Is $[Co(NH_3)_6]^{3+}$ a high-spin complex or a low-spin complex? **(c)** Estimate the wavelength where you expect the absorption of light to reach a maximum? **(d)** What color and magnetic behavior would you predict for the complex ion $[Co(en)_3]^{3+}$?

SOLUTION

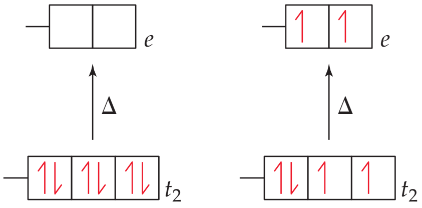
Analyze We are given the color and magnetic behavior of an octahedral complex containing Co with a +3 oxidation number. We need to use this information to determine its electron configuration, its spin state (low-spin or high-spin), and the color of light it absorbs. In part (d), we must use the spectrochemical series to predict how its properties will change if NH_3 is replaced by ethylenediamine (en).

Plan (**a**) From the oxidation number and the periodic table we can determine the number of valence electrons for Co(III) and from that we can determine the electron configuration. (**b**) The magnetic behavior can be used to determine whether this compound is a low-spin or high-spin complex. (**c**) Since there is a single peak in the visible absorption spectrum the color of the compound should be complementary to the color of light that is absorbed most strongly. (**d**) Ethylenediamine is a stronger field ligand than NH_3 so we expect a larger Δ for $[Co(en)_3]^{3+}$ than for $[Co(NH_3)_6]^{3+}$.

Solve

(a) Co has an electron configuration of $[Ar]4s^23d^7$ and Co^{3+} has three fewer electrons than Co. Because transition-metal ions always lose their valence shell *s* electrons, the electron configuration of Co^{3+} is $[Ar]3d^6$.

(b) There are six valence electrons in the *d* orbitals. The filling of the t_2 and *e* orbitals for both high-spin and low-spin complexes is shown below. Because the compound is diamagnetic we know all of the electrons must be paired up, which allows us to determine that $[Co(NH_3)_6]^{3+}$ is a low-spin complex.



Low spin High spin

(c) We are told that the compound is orange and has a single absorption peak in the visible region of the spectrum. The compound must therefore absorb the complementary color of orange, which is blue. The blue region of the spectrum ranges from approximately 430 nm to 490 nm. As an estimate we assume that the complex ion absorbs somewhere in the middle of the blue region, near 460 nm.

(d) Ethylenediammine is higher in the spectrochemical series than ammonia. Therefore, we expect a larger Δ for $[Co(en)_3]^{3+}$. Because Δ was already greater than the spin-pairing energy for $[Co(NH_3)_6]^{3+}$, we expect $[Co(en)_3]^{3+}$ to be a low-spin complex as well, with a d^6 configuration, so it will also be diamagnetic. The wavelength at which the complex absorbs light will shift to higher energy. If we assume a shift in the absorption maximum from blue to violet, the color of the complex will become yellow.

Practice Exercise 1

Which of the following octahedral complex ions will have the fewest number of unpaired electrons? **(a)** $[Cr(H_2O)_6]^{3+}$, **(b)** $[V(H_2O)_6]^{3+}$, **(c)** $[FeF_6]^{3-}$, **(d)** $[RhCl_6]^{3-}$, **(e)** $[Ni(NH_3)_6]^{2+}$.

Practice Exercise 2

Consider the colors of the ammonia complexes of Co^{3+} given in Table 23.3. Based on the change in color would you expect $[Co(NH_3)_5Cl]^{2+}$ to have a larger or smaller value of Δ than $[Co(NH_3)_6]^{3+}$? Is this prediction consistent with the spectrochemical series?

Tetrahedral and Square-Planar Complexes

Thus far we have considered crystal-field theory only for complexes having an octahedral geometry. When there are only four ligands in a complex, the geometry is generally tetrahedral, except for the special case of d^8 metal ions, which we will discuss in a moment.

The crystal-field splitting of *d* orbitals in tetrahedral complexes differs from that in octahedral complexes. Four equivalent ligands can interact with a central metal ion most effectively by approaching along the vertices of a tetrahedron. In this geometry the lobes of the two *e* orbitals point toward the edges of the tetrahedron, exactly in between the ligands (▶ **Figure 23.33**). This orientation keeps the $d_{x^2-y^2}$ and d_{z^2} as far from the ligand point charges as possible. Consequently, these two *d* orbitals experience less repulsion from the ligands and lie at lower energy than the other three *d* orbitals. The three t_2 orbitals do not point directly at the ligand point charges, but they do come closer to the ligands than the *e* set and as a result they experience more repulsion and are higher in energy. As we see in Figure 23.33, the splitting of *d* orbitals in a tetrahedral geometry is the opposite of what we find for the octahedral geometry, namely the *e* orbitals are now *below* the t_2 orbitals. The crystal-field splitting energy Δ is much smaller for tetrahedral complexes than it is for comparable octahedral complexes, in part because there are fewer ligand point charges in the tetrahedral geometry, and in part because neither set of orbitals have lobes that point directly at the ligand point charges. Calculations show that for the same metal ion and ligand set, Δ for the tetrahedral complex is only four-ninths as large as for the octahedral complex. For this reason,

▲ **Figure 23.33** **Energies of the *d* orbitals in a tetrahedral crystal field.** The splitting of the *e* and t_2 sets of orbitals is inverted with respect to the splitting associated with an octahedral crystal field. The crystal field splitting energy Δ is much smaller than it is in an octahedral crystal field.

all tetrahedral complexes are high spin; the crystal-field splitting energy is never large enough to overcome the spin-pairing energies.

In a square-planar complex, four ligands are arranged about the metal ion such that all five species are in the *xy* plane. The resulting energy levels of the *d* orbitals are illustrated in ▶ **Figure 23.34**. Note in particular that the d_{z^2} orbital is considerably lower in energy than the $d_{x^2-y^2}$ orbital. To understand why this is so, recall from Figure 23.28 that in an octahedral field the d_{z^2} orbital of the metal ion interacts with the ligands positioned above and below the *xy* plane. There are no ligands in these two positions in a square-planar complex, which means that the d_{z^2} orbital experiences less repulsion and so remains in a lower-energy, more stable state.

Square-planar complexes are characteristic of metal ions with a d^8 electron configuration. They are nearly always low spin, with the eight *d* electrons spin-paired to form a diamagnetic complex. This pairing leaves the $d_{x^2-y^2}$ orbital empty. Such an electronic arrangement is particularly common among the d^8 ions of periods 5 and 6, such as Pd^{2+}, Pt^{2+}, Ir^{+}, and Au^{3+}.

Give It Some Thought

Why is the energy of the d_{xz} and d_{yz} orbitals in a square-planar complex lower than that of the d_{xy} orbital?

SAMPLE EXERCISE 23.8 Populating *d* Orbitals in Tetrahedral and Square-Planar Complexes

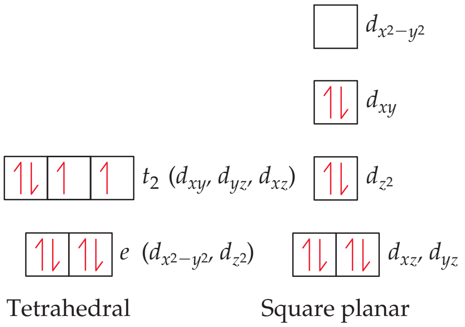
Nickel(II) complexes in which the metal coordination number is 4 can have either square-planar or tetrahedral geometry. $[NiCl_4]^{2-}$ is paramagnetic, and $[Ni(CN)_4]^{2-}$ is diamagnetic. One of these complexes is square planar, and the other is tetrahedral. Use the relevant crystal-field splitting diagrams in the text to determine which complex has which geometry.

SOLUTION

Analyze We are given two complexes containing Ni^{2+} and their magnetic properties. We are given two molecular geometry choices and asked to use crystal-field splitting diagrams from the text to determine which complex has which geometry.

Plan We need to determine the number of *d* electrons in Ni^{2+} and then use Figure 23.33 for the tetrahedral complex and Figure 23.34 for the square-planar complex.

Solve Nickel(II) has the electron configuration $[\mathrm{Ar}]3d^8$. Tetrahedral complexes are always high spin, and square-planar complexes are almost always low spin. Therefore, the population of the *d* electrons in the two geometries is



The tetrahedral complex has two unpaired electrons, and the square-planar complex has none. We know from Section 23.1 that the tetrahedral complex must be paramagnetic and the square planar must be diamagnetic. Therefore, $[\mathrm{NiCl_4}]^{2-}$ is tetrahedral, and $[\mathrm{Ni(CN)_4}]^{2-}$ is square planar.

Comment Nickel(II) forms octahedral complexes more frequently than square-planar ones, whereas d^8 metals from periods 5 and 6 tend to favor square-planar coordination.

Practice Exercise 1

How many unpaired electrons do you predict for the tetrahedral $[\mathrm{MnCl_4}]^{2-}$ ion? **(a)** 1, **(b)** 2, **(c)** 3, **(d)** 4, **(e)** 5.

Practice Exercise 2

Are there any diamagnetic tetrahedral complexes containing transition metal ions with partially filled *d* orbitals? If so what electron count(s) leads to diamagnetism?

Crystal-field theory can be used to explain many observations in addition to those we have discussed. The theory is based on electrostatic interactions between ions and atoms, which essentially means ionic bonds. Many lines of evidence show, however, that the bonding in complexes must have some covalent character. Therefore, molecular-orbital theory (Sections 9.7 and 9.8) can also be used to describe the bonding in complexes, although the application of molecular-orbital theory to coordination compounds is beyond the scope of our discussion. Crystal-field theory, although not entirely accurate in all details, provides an adequate and useful first description of the electronic structure of complexes.

A Closer Look

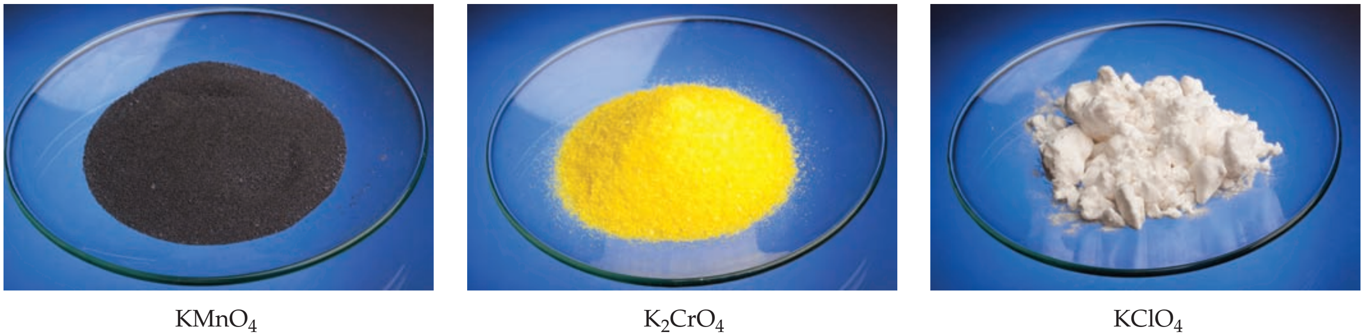
Charge-Transfer Color

In the laboratory portion of your course, you have probably seen many colorful transition-metal compounds, including those shown in ▼ **Figure 23.35**. Many of these compounds are colored because of *d-d* transitions. Some colored complexes, however, including the violet permanganate ion, $\mathrm{MnO_4}^-$, and the yellow chromate ion, $\mathrm{CrO_4}^{2-}$, derive their color from a different type of excitation involving the *d* orbitals.

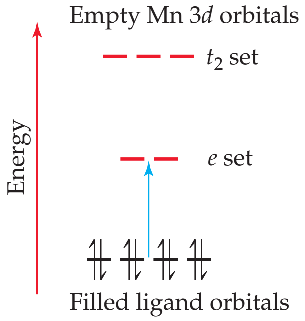
The permanganate ion strongly absorbs visible light, with a maximum absorption at 565 nm. Because violet is complementary to yellow, this strong absorption in the yellow portion of the visible spectrum is responsible for the violet color of salts and solutions of the ion. What is happening during this absorption of light? The $\mathrm{MnO_4}^-$ ion is a complex of Mn(VII). Because Mn(VII) has a d^0 electron configuration, the absorption cannot be due to a *d-d* transition because there are no *d* electrons to excite! That does not mean, however, that the *d* orbitals are not involved in the transition. The excitation in the $\mathrm{MnO_4}^-$ ion is due to a *charge-transfer transition*, in which an electron on one oxygen ligand is excited into a vacant *d* orbital on the Mn ion (▶ **Figure 23.36**). In essence, an electron is transferred from a ligand to the metal, so this transition is called a *ligand-to-metal charge-transfer (LMCT) transition.*

An LMCT transition is also responsible for the color of the $\mathrm{CrO_4}^{2-}$, which is a d^0 Cr(VI) complex.

Also shown in Figure 23.35 is a salt of the perchlorate ion ($\mathrm{ClO_4}^-$). Like $\mathrm{MnO_4}^-$, $\mathrm{ClO_4}^-$ is tetrahedral and has its central atom in the +7 oxidation state. However, because the Cl atom does not have low-lying



▲ **Figure 23.35** **The colors of compounds can arise from charge-transfer transitions.** $\mathrm{KMnO_4}$ and $\mathrm{K_2CrO_4}$ are colored due to ligand-to-metal charge-transfer transitions in their anions. The perchlorate anion in $\mathrm{KClO_4}$ has no occupied *d* orbitals and its charge-transfer transition is at higher energy, corresponding to ultraviolet absorption; therefore it appears white.



▲ **Figure 23.36 Ligand-to-metal charge-transfer transition in MnO_4^-.** As shown by the blue arrow, an electron is excited from a nonbonding pair on O into one of the empty *d* orbitals on Mn.

d orbitals, exciting a Cl electron requires a more energetic photon than does MnO_4^-. The first absorption for ClO_4^- is in the ultraviolet portion of the spectrum, so all the visible light is transmitted and the salt appears white.

Other complexes exhibit charge-transfer excitations in which an electron from the metal atom is excited to an empty orbital on a ligand. Such an excitation is called a *metal-to-ligand charge-transfer (MLCT) transition*.

Charge-transfer transitions are generally more intense than *d-d* transitions. Many metal-containing pigments used for oil painting, such as cadmium yellow (CdS), chrome yellow ($PbCrO_4$), and red ochre (Fe_2O_3), have intense colors because of charge-transfer transitions.

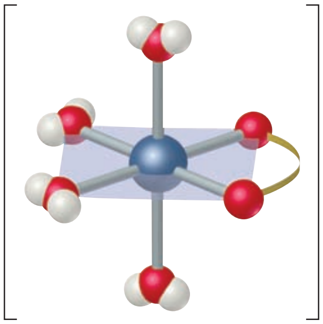
SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

The oxalate ion has the Lewis structure shown in Table 23.4. **(a)** Show the geometry of the complex formed when this ion complexes with cobalt(II) to form $[Co(C_2O_4)(H_2O)_4]$. **(b)** Write the formula for the salt formed when three oxalate ions complex with Co(II), assuming that the charge-balancing cation is Na^+. **(c)** Sketch all the possible geometric isomers for the cobalt complex formed in part (b). Are any of these isomers chiral? Explain. **(d)** The equilibrium constant for the formation of the cobalt(II) complex produced by coordination of three oxalate anions, as in part (b), is 5.0×10^9, and the equilibrium constant for formation of the cobalt(II) complex with three molecules of *ortho*-phenanthroline (Table 23.4) is 9×10^{19}. From these results, what conclusions can you draw regarding the relative Lewis base properties of the two ligands toward cobalt(II)?
(e) Using the approach described in Sample Exercise 17.14, calculate the concentration of free aqueous Co(II) ion in a solution initially containing 0.040 *M* oxalate (*aq*) and 0.0010 *M* $Co^{2+}(aq)$.

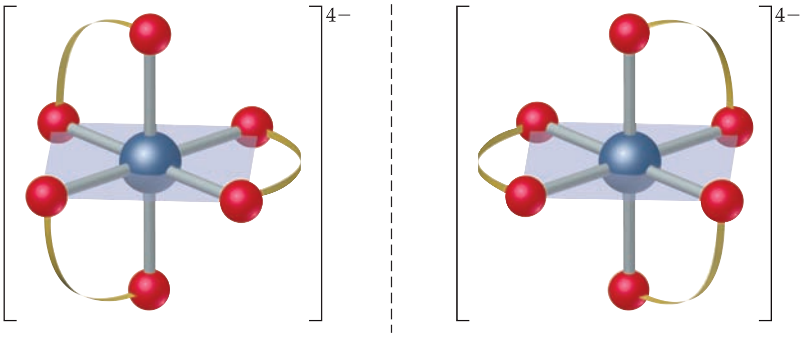
SOLUTION

(a) The complex formed by coordination of one oxalate ion is octahedral:



(b) Because the oxalate ion has a charge of 2−, the net charge of a complex with three oxalate anions and one Co^{2+} ion is 4−. Therefore, the coordination compound has the formula $Na_4[Co(C_2O_4)_3]$.

(c) There is only one geometric isomer. The complex is chiral, however, in the same way the $[Co(en)_3]^{3+}$ complex is chiral (Figure 23.22). The two mirror images are not superimposable, so there are two enantiomers:



(d) The *ortho*-phenanthroline ligand is bidentate, like the oxalate ligand, so they both exhibit the chelate effect. Thus, we conclude that *ortho*-phenanthroline is a stronger Lewis base toward Co^{2+} than oxalate. This conclusion is consistent with what we learned about bases in Section 16.7, that nitrogen bases are generally stronger than oxygen bases. (Recall, for example, that NH_3 is a stronger base than H_2O.)

(e) The equilibrium we must consider involves 3 mol of oxalate ion (represented as Ox^{2-}).

$$Co^{2+}(aq) + 3\,Ox^{2-}(aq) \rightleftharpoons [Co(Ox)_3]^{4-}(aq)$$

The formation-constant expression is

$$K_f = \frac{[[Co(Ox)_3]^{4-}]}{[Co^{2+}][Ox^{2-}]^3}$$

Because K_f is so large, we can assume that essentially all the Co^{2+} is converted to the oxalato complex. Under that assumption, the final concentration of $[Co(Ox)_3]^{4-}$ is 0.0010 M and that of oxalate ion is $[Ox^{2-}] = (0.040) - 3(0.0010) = 0.037\ M$ (three Ox^{2-} ions react with each Co^{2+} ion). We then have

$$[Co^{2+}] = xM,\ [Ox^{2-}] \cong 0.037\ M,\ [[Co(Ox)_3]^{4-}] \cong 0.0010\ M$$

Inserting these values into the equilibrium-constant expression, we have

$$K_f = \frac{(0.0010)}{x(0.037)^3} = 5 \times 10^9$$

Solving for x, we obtain $4 \times 10^{-9}\ M$. From this, we see that the oxalate has complexed all but a tiny fraction of the Co^{2+} in solution.

Chapter Summary and Key Terms

THE TRANSITION METALS (SECTION 23.1) Metallic elements are obtained from **minerals**, which are solid inorganic compounds found in nature. **Metallurgy** is the science and technology of extracting metals from the earth and processing them for further use. Transition metals are characterized by incomplete filling of the *d* orbitals. The presence of *d* electrons in transition elements leads to multiple oxidation states. As we proceed through the transition metals in a given row of the periodic table, the attraction between the nucleus and the valence electrons increases more markedly for *d* electrons than for *s* electrons. As a result, the later transition elements in a period tend to have lower oxidation states.

The atomic and ionic radii of period 5 transition metals are larger than those of period 4 metals. The transition metals of periods 5 and 6 have comparable atomic and ionic radii and are also similar in other properties. This similarity is due to the **lanthanide contraction.**

The presence of unpaired electrons in valence orbitals leads to magnetic behavior in transition metals and their compounds. In **ferromagnetic**, **ferrimagnetic**, and **antiferromagnetic** substances, the unpaired electron spins on atoms in a solid are affected by spins on neighboring atoms. In a ferromagnetic substance the spins all point in the same direction. In an antiferromagnetic substance the spins point in opposite directions and cancel one another. In a ferrimagnetic substance the spins point in opposite directions but do not fully cancel. Ferromagnetic and ferrimagnetic substances are used to make permanent magnets.

TRANSITION-METAL COMPLEXES (SECTION 23.2) **Coordination compounds** are substances that contain **metal complexes**. Metal complexes contain metal ions bonded to several surrounding anions or molecules known as **ligands**. The metal ion and its ligands make up the **coordination sphere** of the complex. The number of atoms attached to the metal ion is the **coordination number** of the metal ion. The most common coordination numbers are 4 and 6; the most common coordination geometries are tetrahedral, square planar, and octahedral.

COMMON LIGANDS IN COORDINATION CHEMISTRY (SECTION 23.3) Ligands that occupy only one site in a coordination sphere are called **monodentate ligands**. The atom of the ligand that bonds to the metal ion is the **donor atom**. Ligands that have two donor atoms are **bidentate ligands**. **Polydentate ligands** have three or more donor atoms. Bidentate and polydendate ligands are also called **chelating agents**. In general, chelating agents form more stable complexes than do related monodentate ligands, an observation known as the **chelate effect**. Many biologically important molecules, such as the **porphyrins**, are complexes of chelating agents. A related group of plant pigments known as **chlorophylls** are important in **photosynthesis**, the process by which plants use solar energy to convert CO_2 and H_2O into carbohydrates.

NOMENCLATURE AND ISOMERISM IN COORDINATION CHEMISTRY (SECTION 23.4) In naming coordination compounds, the number and type of ligands attached to the metal ion are specified, as is the oxidation state of the metal ion. **Isomers** are compounds with the same composition but different arrangements of atoms and therefore different properties. **Structural isomers** differ in the bonding arrangements of the ligands. **Linkage isomerism** occurs when a ligand can coordinate to a metal ion through different donor atoms. **Coordination-sphere isomers** contain different ligands in the coordination sphere. **Stereoisomers** are isomers with the same chemical bonding arrangements but different spatial arrangements of ligands. The most common forms of stereoisomerism are **geometric isomerism** and **optical isomerism**. Geometric isomers differ from one another in the relative locations of donor atoms in the coordination sphere; the most common are cis–trans isomers. Geometric isomers differ from one another in their chemical and physical properties. Optical isomers are nonsuperimposable mirror images of each other. Optical isomers, or **enantiomers**, are **chiral**, meaning that they have a specific "handedness" and differ only in the presence of a chiral environment. Optical isomers can be distinguished from one another by their interactions with plane-polarized light; solutions of one isomer rotate the plane of polarization to the right (**dextrorotatory**), and solutions of its mirror image rotate the plane to the left (**levorotatory**). Chiral molecules, therefore, are **optically active**. A 50–50 mixture of two optical isomers does not rotate plane-polarized light and is said to be **racemic**.

COLOR AND MAGNETISM IN COORDINATION CHEMISTRY (SECTION 23.5) A substance has a particular color because it either reflects or transmits light of that color or absorbs light of the **complementary color**. The amount of light absorbed by a sample as a function of wavelength is known as its **absorption spectrum**. The light absorbed provides the energy to excite electrons to higher-energy states.

It is possible to determine the number of unpaired electrons in a complex from its degree of paramagnetism. Compounds with no unpaired electrons are diamagnetic.

CRYSTAL-FIELD THEORY (SECTION 23.6) **Crystal-field theory** successfully accounts for many properties of coordination compounds, including their color and magnetism. In crystal-field theory, the interaction between metal ion and ligand is viewed as electrostatic. Because some *d* orbitals point directly at the ligands whereas others point between them, the ligands split the energies of the metal *d* orbitals. For an octahedral complex, the *d* orbitals are split into a lower-energy set of three degenerate orbitals (the t_2 set) and a higher-energy set of two degenerate orbitals (the *e* set). Visible light can cause a ***d*-*d* transition**, in which an electron is excited from a lower-energy *d* orbital to a higher-energy *d* orbital. The **spectrochemical series** lists ligands in order of their ability to increase the split in *d*-orbital energies in octahedral complexes.

Strong-field ligands create a splitting of *d*-orbital energies that is large enough to overcome the **spin-pairing energy**. The *d* electrons then preferentially pair up in the lower-energy orbitals, producing a **low-spin complex**. When the ligands exert a weak crystal field, the splitting of the *d* orbitals is small. The electrons then occupy the higher-energy *d* orbitals in preference to pairing up in the lower-energy set, producing a **high-spin complex**.

Crystal-field theory also applies to tetrahedral and square-planar complexes, which leads to different *d*-orbital splitting patterns. In a tetrahedral crystal field, the splitting of the *d* orbitals results in a higher-energy t_2 set and a lower-energy *e* set, the opposite of the octahedral case. The splitting in a tetrahedral crystal field is much smaller than that in an octahedral crystal field, so tetrahedral complexes are always high-spin complexes.

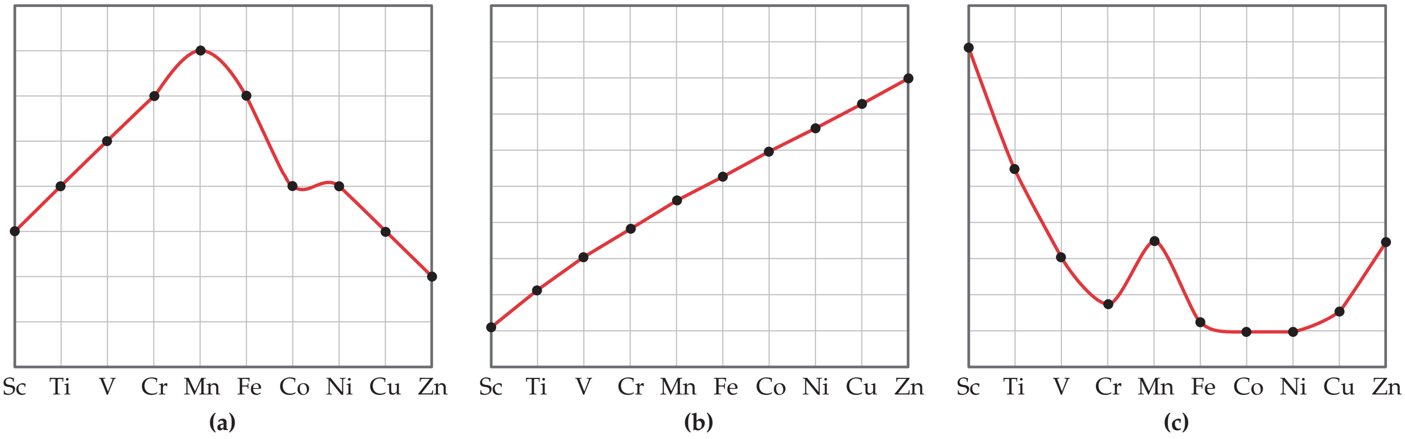
Learning Outcomes After studying this chapter, you should be able to:

- Describe the periodic trends in radii and oxidation states of the transition-metal ions, including the origin and effect of the lanthanide contraction. (Section 23.1)
- Determine the oxidation number and number of *d* electrons for metal ions in complexes. (Section 23.2)
- Identify common ligands and distinguish between chelating and nonchelating ligands. (Section 23.3)
- Name coordination compounds given their formula and write their formula given their name. (Section 23.4)
- Recognize and draw the geometric isomers of a complex. (Section 23.4)
- Recognize and draw the optical isomers of a complex. (Section 23.4)
- Use crystal-field theory to explain the colors and to determine the number of unpaired electrons in a complex. (Sections 23.5 and 23.6)

Exercises

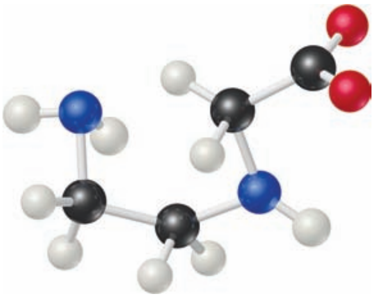
Visualizing Concepts

23.1 The three graphs below show the variation in radius, effective nuclear charge, and maximum oxidation state for the transition metals of period 4. In each part below identify which property is being plotted. [Section 23.1]



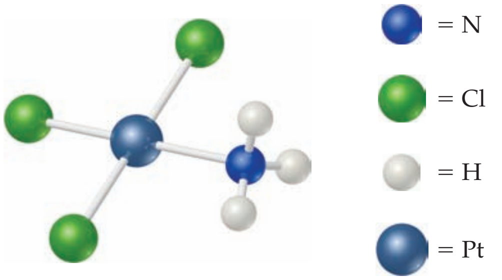
23.2 Draw the structure for Pt(en)Cl_2 and use it to answer the following questions: **(a)** What is the coordination number for platinum in this complex? **(b)** What is the coordination geometry? **(c)** What is the oxidation state of the platinum? **(d)** How many unpaired electrons are there? [Sections 23.2 and 23.6]

23.3 Draw the Lewis structure for the ligand shown here. **(a)** Which atoms can serve as donor atoms? Classify this ligand as monodentate, bidentate, or polydentate. **(b)** How many of these ligands are needed to fill the coordination sphere in an octahedral complex? [Section 23.2]

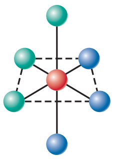


$NH_2CH_2CH_2NHCH_2CO_2^-$

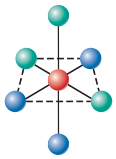
23.4 The complex ion shown here has a 1− charge. Name the complex ion. [Section 23.4]



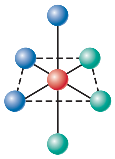
23.5 There are two geometric isomers of octahedral complexes of the type MA_3X_3, where M is a metal and A and X are monodentate ligands. Of the complexes shown here, which are identical to (1) and which are the geometric isomers of (1)? [Section 23.4]



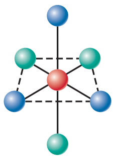
(1)



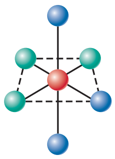
(2)



(3)



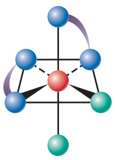
(4)



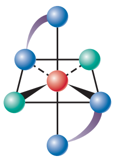
(5)

23.6 Which of the complexes shown here are chiral? [Section 23.4]

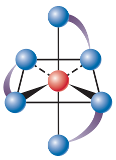
● = Cr ●⌒● = $NH_2CH_2CH_2NH_2$ ● = Cl ● = NH_3



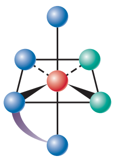
(1)



(2)

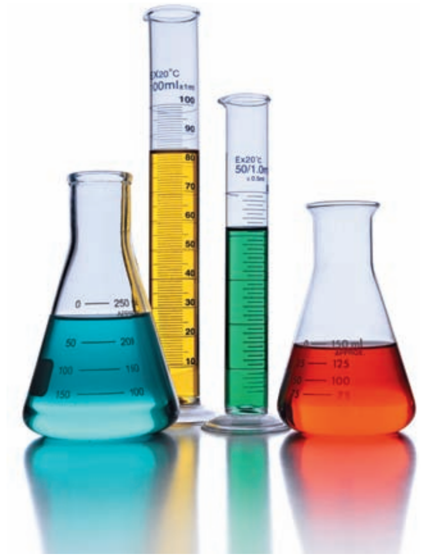


(3)

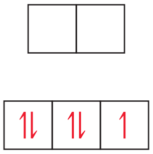


(4)

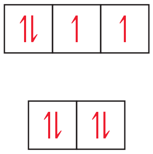
23.7 The solutions shown here each have an absorption spectrum with a single absorption peak like that shown in Figure 23.26. What color does each solution absorb most strongly? [Section 23.5]



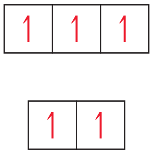
23.8 Which of these crystal-field splitting diagrams represents: **(a)** a weak-field octahedral complex of Fe^{3+}, **(b)** a strong-field octahedral complex of Fe^{3+}, **(c)** a tetrahedral complex of Fe^{3+}, **(d)** a tetrahedral complex of Ni^{2+}? (The diagrams do not indicate the relative magnitudes of Δ.) [Section 23.6]



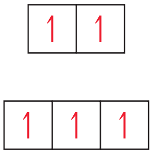
(1)



(2)

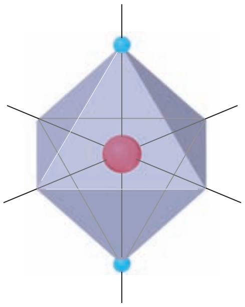


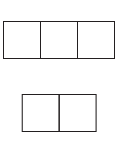
(3)



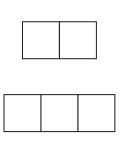
(4)

23.9 In the linear crystal field shown here, the negative charges are on the *z*-axis. Using Figure 23.28 as a guide, predict which of the following choices most accurately describes the splitting of the *d* orbitals in a linear crystal field? [Section 23.6]

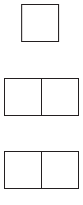




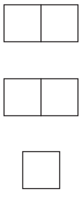
(a)



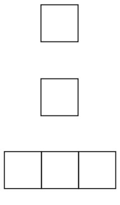
(b)



(c)



(d)



(e)

23.10 Two Fe(II) complexes are both low spin but have different ligands. A solution of one is green and a solution of the other is red. Which solution is likely to contain the complex that has the stronger-field ligand? [Section 23.6]

The Transition Metals (Section 23.1)

23.11 The lanthanide contraction explains which of the following periodic trends? **(a)** The atomic radii of the transition metals first decrease and then increase when moving horizontally across each period. **(b)** When forming ions the transition metals lose their valence *s* orbitals before their valence *d* orbitals. **(c)** The radii of the period 5 transition metals (Y–Cd) are very similar to the radii of the period 6 transition metals (Lu–Hg).

23.12 Which periodic trend is responsible for the observation that the maximum oxidation state of the transition-metal elements peaks near groups 7B and 8B? **(a)** The number of valence electrons reaches a maximum at group 8B. **(b)** The effective nuclear charge increases on moving left across each period. **(c)** The radii of the transition-metal elements reaches a minimum for group 8B and as the size of the atoms decreases it becomes easier to remove electrons.

23.13 For each of the following compounds determine the electron configuration of the transition metal ion. **(a)** TiO, **(b)** TiO_2, **(c)** NiO, **(d)** ZnO.

23.14 Among the period 4 transition metals (Sc–Zn), which elements do not form ions where there are partially filled 3*d* orbitals?

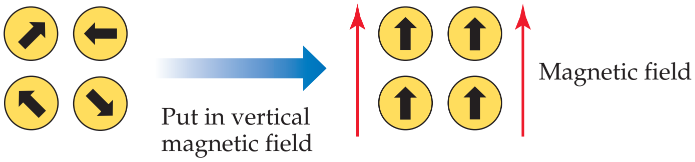
23.15 Write out the ground-state electron configurations of **(a)** Ti^{3+}, **(b)** Ru^{2+}, **(c)** Au^{3+}, **(d)** Mn^{4+}.

23.16 How many electrons are in the valence *d* orbitals in these transition-metal ions? **(a)** Co^{3+}, **(b)** Cu^{+}, **(c)** Cd^{2+}, **(d)** Os^{3+}.

23.17 Which type of substance is attracted by a magnetic field, a diamagnetic substance or a paramagnetic substance?

23.18 Which type of magnetic material cannot be used to make permanent magnets, a ferromagnetic substance, an antiferromagnetic substance, or a ferrimagnetic substance?

23.19 What kind of magnetism is exhibited by this diagram:



23.20 The most important oxides of iron are magnetite, Fe_3O_4, and hematite, Fe_2O_3. **(a)** What are the oxidation states of iron in these compounds? **(b)** One of these iron oxides is ferrimagnetic, and the other is antiferromagnetic. Which iron oxide is likely to show which type of magnetism? Explain.

Transition-Metal Complexes (Section 23.2)

23.21 **(a)** Using Werner's definition of valence, which property is the same as oxidation number, *primary valence* or *secondary valence*? **(b)** What term do we normally use for the other type of valence? **(c)** Why can the NH_3 molecule serve as a ligand but the BH_3 molecule cannot?

23.22 **(a)** What is the meaning of the term *coordination number* as it applies to metal complexes? **(b)** Give an example of a ligand that is neutral and one that is negatively charged. **(c)** Would you expect ligands that are positively charged to be common? Explain. **(d)** What type of chemical bonding is characteristic of coordination compounds? Illustrate with the compound $Co(NH_3)_6Cl_3$. **(e)** What are the most common coordination numbers for metal complexes?

23.23 A complex is written as $NiBr_2 \cdot 6\,NH_3$. **(a)** What is the oxidation state of the Ni atom in this complex? **(b)** What is the likely coordination number for the complex? **(c)** If the complex is treated with excess $AgNO_3(aq)$, how many moles of AgBr will precipitate per mole of complex?

23.24 Crystals of hydrated chromium(III) chloride are green, have an empirical formula of $CrCl_3 \cdot 6\,H_2O$, and are highly soluble, **(a)** Write the complex ion that exists in this compound. **(b)** If the complex is treated with excess $AgNO_3(aq)$, how many moles of AgCl will precipitate per mole of $CrCl_3 \cdot 6\,H_2O$ dissolved in solution? **(c)** Crystals of anhydrous chromium(III) chloride are violet and insoluble in aqueous solution. The coordination geometry of chromium in these crystals is octahedral as is almost always the case for Cr^{3+}. How can this be the case if the ratio of Cr to Cl is not 1:6?

23.25 Indicate the coordination number and the oxidation number of the metal for each of the following complexes:

(a) $Na_2[CdCl_4]$

(b) $K_2[MoOCl_4]$

(c) $[Co(NH_3)_4Cl_2]Cl$

(d) $[Ni(CN)_5]^{3-}$

(e) $K_3[V(C_2O_4)_3]$

(f) $[Zn(en)_2]Br_2$

23.26 Indicate the coordination number and the oxidation number of the metal for each of the following complexes:

(a) $K_3[Co(CN)_6]$

(b) $Na_2[CdBr_4]$

(c) $[Pt(en)_3](ClO_4)_4$

(d) $[Co(en)_2(C_2O_4)]^{+}$

(e) $NH_4[Cr(NH_3)_2(NCS)_4]$

(f) $[Cu(bipy)_2I]I$

Common Ligands in Coordination Chemistry (Section 23.3)

23.27 **(a)** What is the difference between a monodentate ligand and a bidentate ligand? **(b)** How many bidentate ligands are necessary to fill the coordination sphere of a six-coordinate complex? **(c)** You are told that a certain molecule can serve as a tridentate ligand. Based on this statement, what do you know about the molecule?

23.28 For each of the following polydentate ligands, determine (i) the maximum number of coordination sites that the ligand can occupy on a single metal ion and (ii) the number and type of donor atoms in the ligand: **(a)** ethylenediamine (en), **(b)** bipyridine (bipy), **(c)** the oxalate anion ($C_2O_4^{2-}$), **(d)** the 2− ion of the porphine molecule (Figure 23.13), **(e)** $[EDTA]^{4-}$.

23.29 Polydentate ligands can vary in the number of coordination positions they occupy. In each of the following, identify the polydentate ligand present and indicate the probable number of coordination positions it occupies:

(a) $[Co(NH_3)_4(o\text{-phen})]Cl_3$

(b) $[Cr(C_2O_4)(H_2O)_4]Br$

(c) $[Cr(EDTA)(H_2O)]^-$

(d) $[Zn(en)_2](ClO_4)_2$

23.30 Indicate the likely coordination number of the metal in each of the following complexes:

(a) $[Rh(bipy)_3](NO_3)_3$

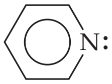
(b) $Na_3[Co(C_2O_4)_2Cl_2]$

(c) $[Cr(o\text{-}phen)_3](CH_3COO)_3$

(d) $Na_2[Co(EDTA)Br]$

23.31 **(a)** What is meant by the term *chelate effect*? **(b)** What thermodynamic factor is generally responsible for the chelate effect? **(c)** Why are polydentate ligands often called *sequestering agents*?

23.32 *Pyridine* (C_5H_5N), abbreviated py, is the molecule

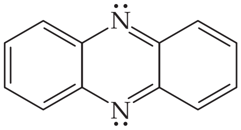


(a) Why is pyridine referred to as a monodentate ligand? **(b)** For the equilibrium reaction

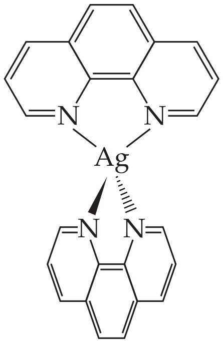
$$[Ru(py)_4(bipy)]^{2+} + 2\ py \rightleftharpoons [Ru(py)_6]^{2+} + bipy$$

what would you predict for the magnitude of the equilibrium constant? Explain your answer.

23.33 True or false? The following ligand can act as a bidentate ligand?



23.34 When silver nitrate is reacted with the molecular base *ortho*-phenanthroline, colorless crystals form that contain the transition-metal complex shown below. **(a)** What is the coordination geometry of silver in this complex? **(b)** Assuming no oxidation or reduction occurs during the reaction, what is charge of the complex shown here? **(c)** Do you expect any nitrate ions will be present in the crystal? **(d)** Write a formula for the compound that forms in this reaction. **(e)** Use the accepted nomenclature to write the name of this compound.



Nomenclature and Isomerism in Coordination Chemistry (Section 23.4)

23.35 Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:

(a) hexaamminechromium(III) nitrate

(b) tetraamminecarbonatocobalt(III) sulfate

(c) dichlorobis(ethylenediamine)platinum(IV) bromide

(d) potassium diaquatetrabromovanadate(III)

(e) bis(ethylenediamine)zinc(II) tetraiodomercurate(II)

23.36 Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:

(a) tetraaquadibromomanganese(III) perchlorate

(b) bis(bipyridyl)cadmium(II) chloride

(c) potassium tetrabromo(*ortho*-phenanthroline)-cobaltate (III)

(d) cesium diamminetetracyanochromate(III)

(e) tris(ethylenediamine)rhodium(III) tris(oxalato)-cobaltate(III)

23.37 Write the names of the following compounds, using the standard nomenclature rules for coordination complexes:

(a) $[Rh(NH_3)_4Cl_2]Cl$

(b) $K_2[TiCl_6]$

(c) $MoOCl_4$

(d) $[Pt(H_2O)_4(C_2O_4)]Br_2$

23.38 Write names for the following coordination compounds:

(a) $[Cd(en)Cl_2]$

(b) $K_4[Mn(CN)_6]$

(c) $[Cr(NH_3)_5(CO_3)]Cl$

(d) $[Ir(NH_3)_4(H_2O)_2](NO_3)_3$

23.39 Consider the following three complexes:

(Complex 1) $[Co(NH_3)_4Br_2]Cl$

(Complex 2) $[Pd(NH_3)_2(ONO)_2]$

(Complex 3) $[V(en)_2Cl_2]^+$,

Which of the three complexes can have **(a)** geometric isomers, **(b)** linkage isomers, **(c)** optical isomers, **(d)** coordination-sphere isomers?

23.40 Consider the following three complexes:

(Complex 1) $[Co(NH_3)_5SCN]^{2+}$

(Complex 2) $[Co(NH_3)_3Cl_3]^{2+}$

(Complex 3) $CoClBr \cdot 5NH_3$

Which of the three complexes can have **(a)** geometric isomers, **(b)** linkage isomers, **(c)** optical isomers, **(d)** coordination-sphere isomers?

23.41 A four-coordinate complex MA_2B_2 is prepared and found to have two different isomers. Is it possible to determine from this information whether the complex is square planar or tetrahedral? If so, which is it?

23.42 Consider an octahedral complex MA_3B_3. How many geometric isomers are expected for this compound? Will any of the isomers be optically active? If so, which ones?

23.43 Sketch all the possible stereoisomers of **(a)** tetrahedral $[Cd(H_2O)_2Cl_2]$, **(b)** square-planar $[IrCl_2(PH_3)_2]^-$, **(c)** octahedral $[Fe(o\text{-}phen)_2Cl_2]^+$.

23.44 Sketch all the possible stereoisomers of **(a)** $[Rh(bipy)(o{-}phen)_2]^{3+}$, **(b)** $[Co(NH_3)_3(bipy)Br]^{2+}$, **(c)** square-planar $[Pd(en)(CN)_2]$.

Color and Magnetism in Coordination Chemistry; Crystal-Field Theory (Sections 23.5 and 23.6)

23.45 **(a)** If a complex absorbs light at 610 nm, what color would you expect the complex to be? **(b)** What is the energy in Joules of a photon with a wavelength of 610 nm? **(c)** What is the energy of this absorption in kJ/mol?

23.46 **(a)** A complex absorbs photons with an energy of 4.51×10^{-19} J. What is the wavelength of these photons? **(b)** If this is the only place in the visible spectrum where the complex absorbs light, what color would you expect the complex to be?

23.47 Identify each of the following coordination complexes as either diamagnetic or paramagnetic:

(a) $[ZnCl_4]^{2-}$

(b) $[Pd(NH_3)_2Cl_2]$

(c) $[V(H_2O)_6]^{3+}$

(d) $[Ni(en)_3]^{2+}$

23.48 Identify each of the following coordination complexes as either diamagnetic or paramagnetic:

(a) $[Ag(NH_3)_2]^+$

(b) square planar $[Cu(NH_3)_4]^{2+}$

(c) $[Ru(bipy)_3]^{2+}$

(d) $[CoCl_4]^{2-}$

23.49 In crystal-field theory, ligands are modeled as if they are point negative charges. What is the basis of this assumption, and how does it relate to the nature of metal–ligand bonds?

23.50 The lobes of which *d* orbitals point directly between the ligands in **(a)** octahedral geometry, **(b)** tetrahedral geometry?

23.51 **(a)** Sketch a diagram that shows the definition of the *crystal-field splitting energy* (Δ) for an octahedral crystal field. **(b)** What is the relationship between the magnitude of Δ and the energy of the *d-d* transition for a d^1 complex? **(c)** Calculate Δ in kJ/mol if a d^1 complex has an absorption maximum at 545 nm.

23.52 As shown in Figure 23.26, the *d-d* transition of $[Ti(H_2O)_6]^{3+}$ produces an absorption maximum at a wavelength of about 500 nm. **(a)** What is the magnitude of Δ for $[Ti(H_2O)_6]^{3+}$ in kJ/mol? **(b)** How would the magnitude of Δ change if the H_2O ligands in $[Ti(H_2O)_6]^{3+}$ were replaced with NH_3 ligands?

23.53 The colors in the copper-containing minerals malachite (green) and azurite (blue) come from a single *d-d* transition in each compound. **(a)** What is the electron configuration of the copper ion in these minerals? **(b)** Based on their colors in which compound would you predict the crystal field splitting Δ is larger?

23.54 The color and wavelength of the absorption maximum for $[Ni(H_2O)_6]^{2+}$, $[Ni(NH_3)_6]^{2+}$, and $[Ni(en)_3]^{2+}$ are given in Figure 23.30. The absorption maximum for the $[Ni(bipy)_3]^{2+}$ ion occurs at about 520 nm. **(a)** What color would you expect for the $[Ni(bipy)_3]^{2+}$ ion? **(b)** Based on these data, where would you put bipy in the spectrochemical series?

23.55 Give the number of (valence) *d* electrons associated with the central metal ion in each of the following complexes: **(a)** $K_3[TiCl_6]$, **(b)** $Na_3[Co(NO_2)_6]$, **(c)** $[Ru(en)_3]Br_3$, **(d)** $[Mo(EDTA)]ClO_4$, **(e)** $K_3[ReCl_6]$.

23.56 Give the number of (valence) *d* electrons associated with the central metal ion in each of the following complexes: **(a)** $K_3[Fe(CN)_6]$, **(b)** $[Mn(H_2O)_6](NO_3)_2$, **(c)** $Na[Ag(CN)_2]$, **(d)** $[Cr(NH_3)_4Br_2]ClO_4$, **(e)** $[Sr(EDTA)]^{2-}$.

23.57 A classmate says, "A weak-field ligand usually means the complex is high spin." Is your classmate correct? Explain.

23.58 A classmate says, "A strong-field ligand means that the ligand binds strongly to the metal ion." Is your classmate correct? Explain.

23.59 For each of the following metals, write the electronic configuration of the atom and its 2+ ion: **(a)** Mn, **(b)** Ru, **(c)** Rh. Draw the crystal-field energy-level diagram for the *d* orbitals of an octahedral complex, and show the placement of the *d* electrons for each 2+ ion, assuming a strong-field complex. How many unpaired electrons are there in each case?

23.60 For each of the following metals, write the electronic configuration of the atom and its 3+ ion: **(a)** Fe, **(b)** Mo, **(c)** Co. Draw the crystal-field energy-level diagram for the *d* orbitals of an octahedral complex, and show the placement of the *d* electrons for each 3+ ion, assuming a weak-field complex. How many unpaired electrons are there in each case?

23.61 Draw the crystal-field energy-level diagrams and show the placement of *d* electrons for each of the following: **(a)** $[Cr(H_2O)_6]^{2+}$ (four unpaired electrons), **(b)** $[Mn(H_2O)_6]^{2+}$ (high spin), **(c)** $[Ru(NH_3)_5(H_2O)]^{2+}$ (low spin), **(d)** $[IrCl_6]^{2-}$ (low spin), **(e)** $[Cr(en)_3]^{3+}$, **(f)** $[NiF_6]^{4-}$.

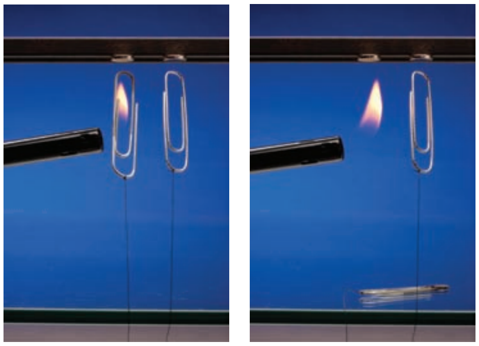
23.62 Draw the crystal-field energy-level diagrams and show the placement of electrons for the following complexes: **(a)** $[VCl_6]^{3-}$, **(b)** $[FeF_6]^{3-}$ (a high-spin complex), **(c)** $[Ru(bipy)_3]^{3+}$ (a low-spin complex), **(d)** $[NiCl_4]^{2-}$ (tetrahedral), **(e)** $[PtBr_6]^{2-}$, **(f)** $[Ti(en)_3]^{2+}$.

23.63 The complex $[Mn(NH_3)_6]^{2+}$ contains five unpaired electrons. Sketch the energy-level diagram for the *d* orbitals, and indicate the placement of electrons for this complex ion. Is the ion a high-spin or a low-spin complex?

23.64 The ion $[Fe(CN)_6]^{3-}$ has one unpaired electron, whereas $[Fe(NCS)_6]^{3-}$ has five unpaired electrons. From these results, what can you conclude about whether each complex is high spin or low spin? What can you say about the placement of NCS^- in the spectrochemical series?

Additional Exercises

23.65 The *Curie temperature* is the temperature at which a ferromagnetic solid switches from ferromagnetic to paramagnetic, and for nickel, the Curie temperature is 354 °C. Knowing this, you tie a string to two paper clips made of nickel and hold the paper clips near a permanent magnet. The magnet attracts the paper clips, as shown in the photograph on the left. Now you heat one of the paper clips with a cigarette lighter, and the clip drops (right photograph). Explain what happened.



23.66 Explain why the transition metals in periods 5 and 6 have nearly identical radii in each group.

23.67 Based on the molar conductance values listed here for the series of platinum(IV) complexes, write the formula for each complex so as to show which ligands are in the coordination sphere of the metal. By way of example, the molar conductances of 0.050 *M* NaCl and $BaCl_2$ are 107 ohm^{-1} and 197 ohm^{-1}, respectively.

Complex	Molar Conductance (ohm^{-1})* of 0.050 *M* Solution
$Pt(NH_3)_6Cl_4$	523
$Pt(NH_3)_4Cl_4$	228
$Pt(NH_3)_3Cl_4$	97
$Pt(NH_3)_2Cl_4$	0
$KPt(NH_3)Cl_5$	108

*The ohm is a unit of resistance; conductance is the inverse of resistance.

23.68 **(a)** A compound with formula $RuCl_3 \cdot 5\,H_2O$ is dissolved in water, forming a solution that is approximately the same color as the solid. Immediately after forming the solution, the addition of excess $AgNO_3(aq)$ forms 2 mol of solid AgCl per mole of complex. Write the formula for the compound, showing which ligands are likely to be present in the coordination sphere. **(b)** After a solution of $RuCl_3 \cdot 5\,H_2O$ has stood for about a year, addition of $AgNO_3(aq)$ precipitates 3 mol of AgCl per mole of complex. What has happened in the ensuing time?

23.69 Sketch the structure of the complex in each of the following compounds and give the full compound name:

(a) *cis*-$[Co(NH_3)_4(H_2O)_2](NO_3)_2$

(b) $Na_2[Ru(H_2O)Cl_5]$

(c) *trans*-$NH_4[Co(C_2O_4)_2(H_2O)_2]$

(d) *cis*-$[Ru(en)_2Cl_2]$

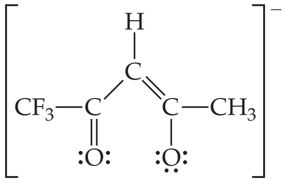
23.70 **(a)** Which complex ions in Exercise 23.69 have a mirror plane? **(b)** Will any of the complexes have optical isomers?

23.71 The molecule *dimethylphosphinoethane* $[(CH_3)_2PCH_2CH_2P(CH_3)_2$, which is abbreviated dmpe] is used as a ligand for some complexes that serve as catalysts. A complex that contains this ligand is $Mo(CO)_4(dmpe)$. **(a)** Draw the Lewis structure for dmpe, and compare it with ethylenediamine as a coordinating ligand. **(b)** What is the oxidation state of Mo in $Na_2[Mo(CN)_2(CO)_2(dmpe)]$? **(c)** Sketch the structure of the $[Mo(CN)_2(CO)_2(dmpe)]^{2-}$ ion, including all the possible isomers.

23.72 Although the cis configuration is known for $[Pt(en)Cl_2]$, no trans form is known. **(a)** Explain why the trans compound is not possible. **(b)** Would $NH_2CH_2CH_2CH_2CH_2NH_2$ be more likely than en $(NH_2CH_2CH_2NH_2)$ to form the trans compound? Explain.

23.73 The acetylacetone ion forms very stable complexes with many metallic ions. It acts as a bidentate ligand, coordinating to the metal at two adjacent positions. Suppose that one of the CH_3 groups of the ligand is replaced by a CF_3 group, as shown here:

Trifluoromethyl
acetylacetonate
(tfac)



Sketch all possible isomers for the complex with three tfac ligands on cobalt(III). (You can use the symbol ●⌒○ to represent the ligand.)

23.74 Which transition metal atom is present in each of the following biologically important molecules: **(a)** hemoglobin, **(b)** chlorophylls, **(c)** siderophores.

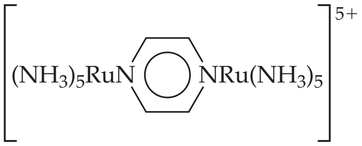
23.75 Carbon monoxide, CO, is an important ligand in coordination chemistry. When CO is reacted with nickel metal the product is $[Ni(CO)_4]$, which is a toxic, pale yellow liquid. **(a)** What is the oxidation number for nickel in this compound? **(b)** Given that $[Ni(CO)_4]$ is diamagnetic molecule with a tetrahedral geometry, what is the electron configuration of nickel in this compound? **(c)** Write the name for $[Ni(CO)_4]$ using the nomenclature rules for coordination compounds.

23.76 Some metal complexes have a coordination number of 5. One such complex is $Fe(CO)_5$, which adopts a *trigonal bipyramidal* geometry (see Figure 9.8). **(a)** Write the name for $Fe(CO)_5$, using the nomenclature rules for coordination compounds. **(b)** What is the oxidation state of Fe in this compound? **(c)** Suppose one of the CO ligands is replaced with a CN^- ligand, forming $[Fe(CO)_4(CN)]^-$. How many geometric isomers would you predict this complex could have?

23.77 Which of the following objects is chiral: **(a)** a left shoe, **(b)** a slice of bread, **(c)** a wood screw, **(d)** a molecular model of $Zn(en)Cl_2$, **(e)** a typical golf club?

23.78 The complexes $[V(H_2O)_6]^{3+}$ and $[VF_6]^{3-}$ are both known. **(a)** Draw the *d*-orbital energy-level diagram for V(III) octahedral complexes. **(b)** What gives rise to the colors of these complexes? **(c)** Which of the two complexes would you expect to absorb light of higher energy?

[23.79] One of the more famous species in coordination chemistry is the Creutz–Taube complex:



It is named for the two scientists who discovered it and initially studied its properties. The central ligand is pyrazine, a planar six-membered ring with nitrogens at opposite sides. **(a)** How can you account for the fact that the complex, which has only neutral ligands, has an odd overall charge? **(b)** The metal is in a low-spin configuration in both cases. Assuming octahedral coordination, draw the *d*-orbital energy-level diagram for each metal. **(c)** In many experiments the two metal ions appear to be in exactly equivalent states. Can you think of a reason that this might appear to be so, recognizing that electrons move very rapidly compared to nuclei?

23.80 Solutions of $[Co(NH_3)_6]^{2+}$, $[Co(H_2O)_6]^{2+}$ (both octahedral), and $[CoCl_4]^{2-}$ (tetrahedral) are colored. One is pink, one is blue, and one is yellow. Based on the spectrochemical series and remembering that the energy splitting in tetrahedral complexes is normally much less than that in octahedral ones, assign a color to each complex.

23.81 Oxyhemoglobin, with an O_2 bound to iron, is a low-spin Fe(II) complex; deoxyhemoglobin, without the O_2 molecule, is a high-spin complex. **(a)** Assuming that the coordination environment about the metal is octahedral, how many unpaired electrons are centered on the metal ion in each case? **(b)** What ligand is coordinated to the iron in place of O_2 in deoxyhemoglobin? **(c)** Explain in a general way why the two forms of hemoglobin have different colors (hemoglobin is red, whereas deoxyhemoglobin has a bluish cast). **(d)** A 15-minute exposure to air containing 400 ppm of CO causes about 10% of the hemoglobin in the blood to be converted into the carbon monoxide complex, called carboxyhemoglobin. What does this suggest about the relative equilibrium constants for binding of carbon monoxide and O_2 to hemoglobin? **(e)** CO is a strong-field ligand. What color might you expect carboxyhemoglobin to be?

[23.82] Consider the tetrahedral anions VO_4^{3-} (orthovanadate ion), CrO_4^{2-} (chromate ion), and MnO_4^- (permanganate ion). **(a)** These anions are *isoelectronic*. What does this statement mean? **(b)** Would you expect these anions to exhibit *d-d* transitions? Explain. **(c)** As mentioned in "A Closer Look" on charge-transfer color, the violet color of MnO_4^- is due to a *ligand-to-metal charge transfer* (LMCT) transition. What is meant by this term? **(d)** The LMCT transition in MnO_4^- occurs at a wavelength of 565 nm. The CrO_4^{2-} ion is yellow. Is the wavelength of the LMCT transition for chromate larger or smaller than that for MnO_4^-? Explain. **(e)** The VO_4^{3-} ion is colorless. Do you expect the light absorbed by the LMCT to fall in the UV or the IR region of the electromagnetic spectrum? Explain your reasoning.

23.83 **(a)** Given the colors observed for VO_4^{3-} (orthovanadate ion), CrO_4^{2-} (chromate ion), and MnO_4^- (permanganate ion) (see Exercise 23.82), what can you say about how the energy separation between the ligand orbitals and the empty *d* orbitals changes as a function of the oxidation state of the transition metal at the center of the tetrahedral anion?

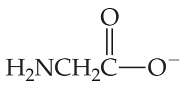
[23.84] The red color of ruby is due to the presence of Cr(III) ions at octahedral sites in the close-packed oxide lattice of Al_2O_3. Draw the crystal-field splitting diagram for Cr(III) in this environment. Suppose that the ruby crystal is subjected to high pressure. What do you predict for the variation in the wavelength of absorption of the ruby as a function of pressure? Explain.

23.85 In 2001, chemists at SUNY-Stony Brook succeeded in synthesizing the complex *trans*-$[Fe(CN)_4(CO)_2]^{2-}$, which could be a model of complexes that may have played a role in the origin of life. **(a)** Sketch the structure of the complex. **(b)** The complex is isolated as a sodium salt. Write the complete name of this salt. **(c)** What is the oxidation state of Fe in this complex? How many *d* electrons are associated with the Fe in this complex? **(d)** Would you expect this complex to be high spin or low spin? Explain.

[23.86] When Alfred Werner was developing the field of coordination chemistry, it was argued by some that the optical activity he observed in the chiral complexes he had prepared was because of the presence of carbon atoms in the molecule. To disprove this argument, Werner synthesized a chiral complex of cobalt that had no carbon atoms in it, and he was able to resolve it into its enantiomers. Design a cobalt(III) complex that would be chiral if it could be synthesized and that contains no carbon atoms. (It may not be possible to synthesize the complex you design, but we will not worry about that for now.)

23.87 Generally speaking, for a given metal and ligand, the stability of a coordination compound is greater for the metal in the +3 rather than in the +2 oxidation state (for metals that form stable +3 ions in the first place). Suggest an explanation, keeping in mind the Lewis acid–base nature of the metal–ligand bond.

23.88 Many trace metal ions exist in the blood complexed with amino acids or small peptides. The anion of the amino acid glycine (gly),



$$H_2NCH_2\overset{\overset{\Large O}{\|}}{C}—O^-$$

can act as a bidentate ligand, coordinating to the metal through nitrogen and oxygen atoms. How many isomers are possible for **(a)** $[Zn(gly)_2]$ (tetrahedral), **(b)** $[Pt(gly)_2]$ (square planar), **(c)** $[Co(gly)_3]$ (octahedral)? Sketch all possible isomers. Use the symbol to represent the ligand.

23.89 The coordination complex $[Cr(CO)_6]$ forms colorless, diamagnetic crystals that melt at 90 °C. **(a)** What is the oxidation number of chromium in this compound? **(b)** Given that $[Cr(CO)_6]$ is diamagnetic, what is the electron configuration of chromium in this compound? **(c)** Given that $[Cr(CO)_6]$ is colorless, would you expect CO to be a weak-field or strong-field ligand? **(d)** Write the name for $[Cr(CO)_6]$ using the nomenclature rules for coordination compounds.

Integrative Exercises

[23.90] Metallic elements are essential components of many important enzymes operating within our bodies. *Carbonic anhydrase*, which contains Zn^{2+} in its active site, is responsible for rapidly interconverting dissolved CO_2 and bicarbonate ion, HCO_3^-. The zinc in carbonic anhydrase is tetrahedrally coordinated by three neutral nitrogen-containing groups and a water molecule. The coordinated water molecule has a pK_a of 7.5, which is crucial for the enzyme's activity. **(a)** Draw the active site geometry for the Zn(II) center in carbonic anhydrase, just writing "N" for the three neutral nitrogen ligands from the protein. **(b)** Compare the pK_a of carbonic anhydrase's active site with that of pure water; which species is more acidic? **(c)** When the coordinated water to the Zn(II) center in carbonic anhydrase is deprotonated, what ligands are bound to the Zn(II) center? Assume the three nitrogen ligands are unaffected. **(d)** The pK_a of $[Zn(H_2O)_6]^{2+}$ is 10. Suggest an explanation for the difference between this pK_a and that of carbonic anhydrase. **(e)** Would you expect carbonic anhydrase to have a deep color, like hemoglobin and other metal-ion containing proteins do? Explain.

23.91 Two different compounds have the formulation $CoBr(SO_4) \cdot 5\,NH_3$. Compound A is dark violet, and compound B is red-violet. When compound A is treated with $AgNO_3(aq)$, no reaction occurs, whereas compound B reacts with $AgNO_3(aq)$ to form a white precipitate. When compound A is treated with $BaCl_2(aq)$, a white precipitate is formed, whereas compound B has no reaction with $BaCl_2(aq)$. **(a)** Is Co in the same oxidation state in these complexes? **(b)** Explain the reactivity of compounds A and B with $AgNO_3(aq)$ and $BaCl_2(aq)$. **(c)** Are compounds A and B isomers of one another? If so, which category from Figure 23.19 best describes the isomerism observed for these complexes? **(d)** Would compounds A and B be expected to be strong electrolytes, weak electrolytes, or nonelectrolytes?

23.92 A manganese complex formed from a solution containing potassium bromide and oxalate ion is purified and analyzed. It contains 10.0% Mn, 28.6% potassium, 8.8% carbon, and 29.2% bromine by mass. The remainder of the compound is oxygen. An aqueous solution of the complex has about the same electrical conductivity as an equimolar solution of $K_4[Fe(CN)_6]$. Write the formula of the compound, using brackets to denote the manganese and its coordination sphere.

23.93 The $E°$ values for two low-spin iron complexes in acidic solution are as follows:

$$[Fe(o\text{-}phen)_3]^{3+}(aq) + e^- \rightleftharpoons Fe(o\text{-}phen)_3]^{2+}(aq) \qquad E° = 1.12\ V$$

$$[Fe(CN)_6]^{3-}(aq) + e^- \rightleftharpoons Fe(CN)_6]^{4-}(aq) \qquad E° = 0.36\ V$$

(a) Is it thermodynamically favorable to reduce both Fe(III) complexes to their Fe(II) analogs? Explain. **(b)** Which complex, $[Fe(o\text{-}phen)_3]^{3+}$ or $[Fe(CN)_6]^{3-}$, is more difficult to reduce? **(c)** Suggest an explanation for your answer to (b).

23.94 A palladium complex formed from a solution containing bromide ion and pyridine, C_5H_5N (a good electron-pair donor), is found on elemental analysis to contain 37.6% bromine, 28.3% carbon, 6.60% nitrogen, and 2.37% hydrogen by mass. The compound is slightly soluble in several organic solvents; its solutions in water or alcohol do not conduct electricity. It is found experimentally to have a zero dipole moment. Write the chemical formula, and indicate its probable structure.

23.95 **(a)** In early studies it was observed that when the complex $[Co(NH_3)_4Br_2]Br$ was placed in water, the electrical conductivity of a 0.05 M solution changed from an initial value of 191 ohm^{-1} to a final value of 374 ohm^{-1} over a period of an hour or so. Suggest an explanation for the observed results. (See Exercise 23.67 for relevant comparison data.) **(b)** Write a balanced chemical equation to describe the reaction. **(c)** A 500-mL solution is made up by dissolving 3.87 g of the complex. As soon as the solution is formed, and before any change in conductivity has occurred, a 25.00-mL portion of the solution is titrated with 0.0100 M $AgNO_3$ solution. What volume of $AgNO_3$ solution do you expect to be required to precipitate the free $Br^-(aq)$? **(d)** Based on the response you gave to part (b), what volume of $AgNO_3$ solution would be required to titrate a fresh 25.00-mL sample of $[Co(NH_3)_4Br_2]Br$ after all conductivity changes have occurred?

23.96 The total concentration of Ca^{2+} and Mg^{2+} in a sample of hard water was determined by titrating a 0.100-L sample of the water with a solution of $EDTA^{4-}$. The $EDTA^{4-}$ chelates the two cations:

$$Mg^{2+} + [EDTA]^{4-} \longrightarrow [Mg(EDTA)]^{2-}$$
$$Ca^{2+} + [EDTA]^{4-} \longrightarrow [Ca(EDTA)]^{2-}$$

It requires 31.5 mL of 0.0104 M $[EDTA]^{4-}$ solution to reach the end point in the titration. A second 0.100-L sample was then treated with sulfate ion to precipitate Ca^{2+} as calcium sulfate. The Mg^{2+} was then titrated with 18.7 mL of 0.0104 M $[EDTA]^{4-}$. Calculate the concentrations of Mg^{2+} and Ca^{2+} in the hard water in mg/L.

23.97 Carbon monoxide is toxic because it binds more strongly to the iron in hemoglobin (Hb) than does O_2, as indicated by these approximate standard free-energy changes in blood:

$$Hb + O_2 \longrightarrow HbO_2 \qquad \Delta G° = -70\ kJ$$
$$Hb + CO \longrightarrow HbCO \qquad \Delta G° = -80\ kJ$$

Using these data, estimate the equilibrium constant at 298 K for the equilibrium

$$HbO_2 + CO \rightleftharpoons HbCO + O_2$$

[23.98] The molecule *methylamine* (CH_3NH_2) can act as a monodentate ligand. The following are equilibrium reactions and the thermochemical data at 298 K for reactions of methylamine and en with $Cd^{2+}(aq)$:

$$Cd^{2+}(aq) + 4\,CH_3NH_2(aq) \rightleftharpoons [Cd(CH_3NH_2)_4]^{2+}(aq)$$
$$\Delta H° = -57.3\ kJ; \quad \Delta S° = -67.3\ J/K; \quad \Delta G° = -37.2\ kJ$$
$$Cd^{2+}(aq) + 2\,en(aq) \rightleftharpoons [Cd(en)_2]^{2+}(aq)$$
$$\Delta H° = -56.5\ kJ; \quad \Delta S° = +14.1\ J/K; \quad \Delta G° = -60.7\ kJ$$

(a) Calculate $\Delta G°$ and the equilibrium constant K for the following *ligand exchange* reaction:

$$[Cd(CH_3NH_2)_4]^{2+}(aq) + 2\,en(aq) \rightleftharpoons [Cd(en)_2]^{2+}(aq) + 4\,CH_3NH_2(aq)$$

Based on the value of K in part (a), what would you conclude about this reaction? What concept is demonstrated? **(b)** Determine the magnitudes of the enthalpic ($\Delta H°$) and the entropic ($-T\Delta S°$) contributions to $\Delta G°$ for the ligand exchange reaction. Explain the relative magnitudes. **(c)** Based on information in this exercise and in the “A Closer Look” box on the chelate effect, predict the sign of $\Delta H°$ for the following hypothetical reaction:

$$[Cd(CH_3NH_2)_4]^{2+}(aq) + 4\,NH_3(aq) \rightleftharpoons [Cd(NH_3)_4]^{2+}(aq) + 4\,CH_3NH_2(aq)$$

23.99 The value of Δ for the $[CrF_6]^{3-}$ complex is 182 kJ/mol. Calculate the expected wavelength of the absorption corresponding to promotion of an electron from the lower-energy to the higher-energy d-orbital set in this complex. Should the complex absorb in the visible range?

[23.100] A Cu electrode is immersed in a solution that is 1.00 M in $[Cu(NH_3)_4]^{2+}$ and 1.00 M in NH_3. When the cathode is a standard hydrogen electrode, the emf of the cell is found to be +0.08 V. What is the formation constant for $[Cu(NH_3)_4]^{2+}$?

[23.101] The complex $[Ru(EDTA)(H_2O)]^-$ undergoes substitution reactions with several ligands, replacing the water molecule with the ligand. In all cases, the ruthenium stays in the +3 oxidation state and the ligands use a nitrogen donor atom to bind to the metal.

$$[Ru(EDTA)(H_2O)]^- + L \longrightarrow [Ru(EDTA)L]^- + H_2O$$

The rate constants for several ligands are as follows:

Ligand, L	**k ($M^{-1}s^{-1}$)**
Pyridine	6.3×10^3
SCN^-	2.7×10^2
CH_3CN	3.0×10

(a) One possible mechanism for this substitution reaction is that the water molecule dissociates from the Ru(III) in the rate-determining step, and then the ligand L binds to Ru(III) in a rapid second step. A second possible mechanism is that L approaches the complex, begins to form a new bond to the Ru(III), and displaces the water molecule, all in a single concerted step. Which of these two mechanisms is more consistent with the data? Explain. **(b)** What do the results suggest about the relative donor ability of the nitrogens of the three ligands toward Ru(III)? **(c)** Assuming that the complexes are all low spin, how many unpaired electrons are in each?

Design an Experiment

Following a procedure found in a scientific paper you go into the lab and attempt to prepare crystals of dichlorobis(ethylenediamine)cobalt(III) chloride. The paper states that this compound can be made by reacting $CoCl_2 \cdot 6\,H_2O$, an excess of ethylenediamine, O_2 from the air (which acts as an oxidizing agent), water, and concentrated hydrochloric acid. At the end of the reaction you filter off the solution and are left with a green, crystalline product. **(a)** What experiment(s) could you perform to confirm that you have prepared $[CoCl_2(en)_2]Cl$ and not $[Co(en)_3]Cl_3$? **(b)** How could you verify that cobalt was present as Co^{3+} and determine the spin state of the cobalt complex in your product? **(c)** How many geometric isomers exist for $[CoCl_2(en)_2]Cl$? How could you determine if your product contains a single geometric isomer or a mixture of geometric isomers? **(d)** If the product does contain a single geometric isomer how would you determine which one was present? (*Hint: You may find the information in Table 23.3 helpful.*)

24

The Chemistry of Life: Organic and Biological Chemistry

We are all familiar with how chemical substances can influence our health and behavior. Aspirin, also known as acetylsalicylic acid, relieves aches and pains. Cocaine, whose full chemical name is methyl (1*R*,2*R*,3*S*,5*S*)-3-(benzoyloxy)-8-methyl-8-azabicyclo[3.2.1]octane-2-carboxylate, is a plant-derived substance that is used in clinical situations as an anesthetic, but also is used illegally to experience extreme euphoria (a “high”).

Understanding how these molecules exert their effects, and developing new molecules that can target disease and pain, is an enormous part of the modern chemical enterprise. This chapter is about the molecules, composed mainly of carbon, hydrogen, oxygen, and nitrogen, that bridge chemistry and biology.

More than 16 million carbon-containing compounds are known. Chemists make thousands of new compounds every year, about 90% of which contain carbon. The study of compounds whose molecules contain carbon constitutes the branch of chemistry known as **organic chemistry**. This term arose from the eighteenth-century belief that organic compounds could be formed only by living (that is, organic) systems. This idea was disproved in 1828 by the German chemist Friedrich Wöhler when he synthesized urea (H_2NCONH_2), an organic substance found in the urine of mammals, by heating ammonium cyanate (NH_4OCN), an inorganic (nonliving) substance.

▶ **BRAIN ON COCAINE.** These positron-emitting tomography (PET) scans of the human brain show how rapidly glucose is metabolized in different parts of the brain. The top row of images show the brain of a normal person; the bottom two rows of images show the brain of a person who has taken cocaine, after 10 days and after 100 days (red = high glucose metabolism, yellow = medium, blue = low). Notice that glucose metabolism is suppressed in the brain of the person who has taken cocaine.

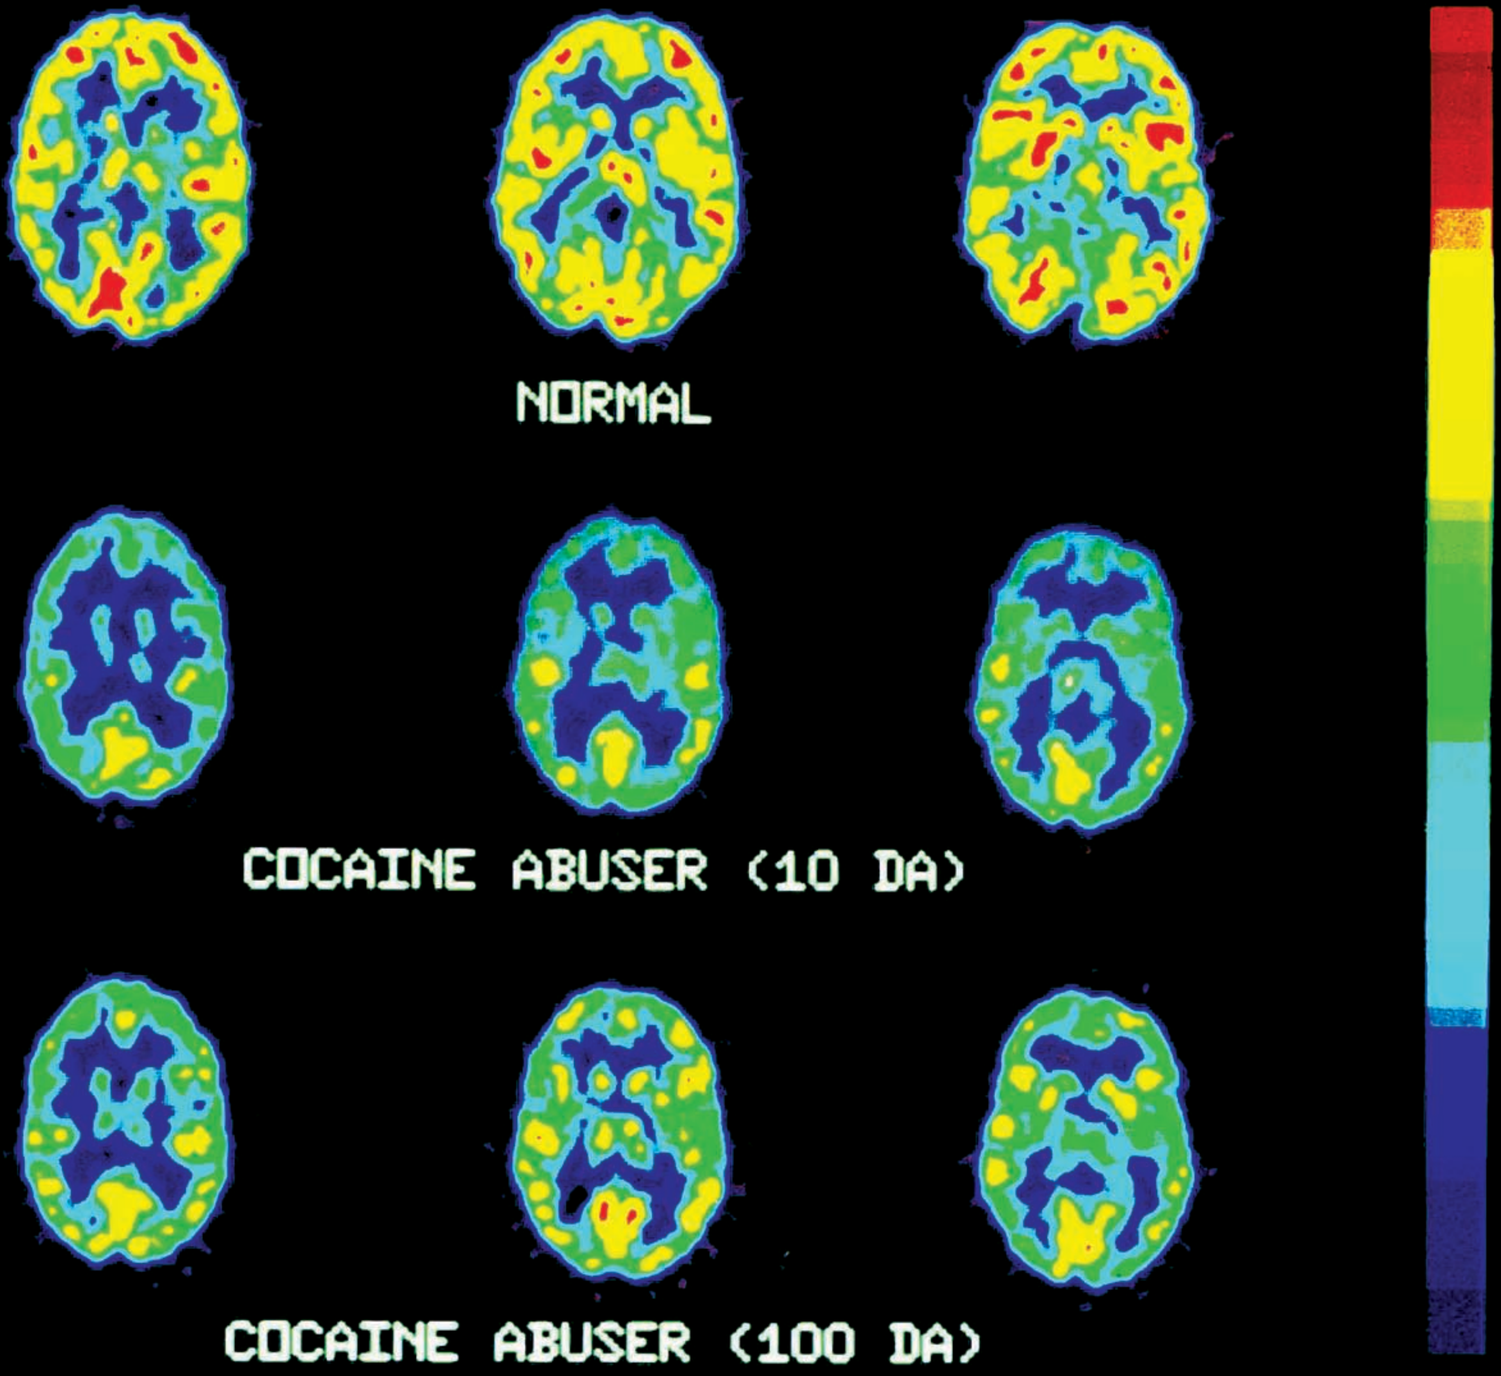
WHAT’S AHEAD

24.1 GENERAL CHARACTERISTICS OF ORGANIC MOLECULES We begin with a review of the structures and properties of organic compounds.

24.2 INTRODUCTION TO HYDROCARBONS We consider *hydrocarbons*, compounds containing only C and H, including the hydrocarbons called *alkanes*, which contain only single $\mathrm{C{-}C}$ bonds. We also look at *isomers*, compounds with identical compositions but different molecular structures.

24.3 ALKENES, ALKYNES, AND AROMATIC HYDROCARBONS We next explore hydrocarbons with one or more $\mathrm{C{=}C}$ bonds, called *alkenes*, and those with one or more $\mathrm{C{\equiv}C}$ bonds, called *alkynes*. *Aromatic* hydrocarbons have at least one planar ring with delocalized π electrons.

24.4 ORGANIC FUNCTIONAL GROUPS We recognize that a central organizing principle of organic chemistry is the *functional group*, a group of atoms at which most of the compound’s chemical reactions occur.



24.5 CHIRALITY IN ORGANIC CHEMISTRY We learn that compounds with nonsuperimposable mirror images are *chiral* and that chirality plays important roles in organic and biological chemistry.

24.6 INTRODUCTION TO BIOCHEMISTRY We introduce the chemistry of living organisms, known as *biochemistry*, *biological chemistry*, or *chemical biology*. Important classes of compounds that occur in living systems are *proteins*, *carbohydrates*, *lipids*, and *nucleic acids*.

24.7 PROTEINS We learn that proteins are polymers of *amino acids* linked with *amide* (also called *peptide*) bonds. Proteins are used by organisms for structural support, as molecular transporters and as catalysts for biochemical reactions.

24.8 CARBOHYDRATES We observe that carbohydrates are sugars and polymers of sugars used primarily as fuel by organisms (glucose) or as structural support in plants (cellulose).

24.9 LIPIDS We find that lipids are a large class of molecules used primarily for energy storage in organisms.

24.10 NUCLEIC ACIDS We learn that nucleic acids are polymers of *nucleotides* that contain an organism's genetic information. *Deoxyribonucleic acid* (DNA) and *ribonucleic acid* (RNA) are polymers composed of nucleotides.

The study of the chemistry of living species is called *biological chemistry*, *chemical biology*, or **biochemistry**. In this chapter, we present some of the elementary aspects of both organic chemistry and biochemistry.

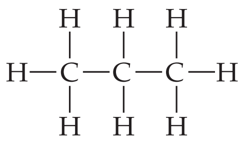
24.1 | General Characteristics of Organic Molecules

What is it about carbon that leads to the tremendous diversity in its compounds and allows it to play such crucial roles in biology and society? Let's consider some general features of organic molecules and, as we do, review principles we learned in earlier chapters.

The Structures of Organic Molecules

Because carbon has four valence electrons ([He]$2s^2 2p^2$), it forms four bonds in virtually all its compounds. When all four bonds are single bonds, the electron pairs are disposed in a tetrahedral arrangement. (Section 9.2) In the hybridization model, the carbon 2*s* and 2*p* orbitals are then sp^3 hybridized. (Section 9.5) When there is one double bond, the arrangement is trigonal planar (sp^2 hybridization). With a triple bond, it is linear (*sp* hybridization). Examples are shown in ▼ **Figure 24.1**.

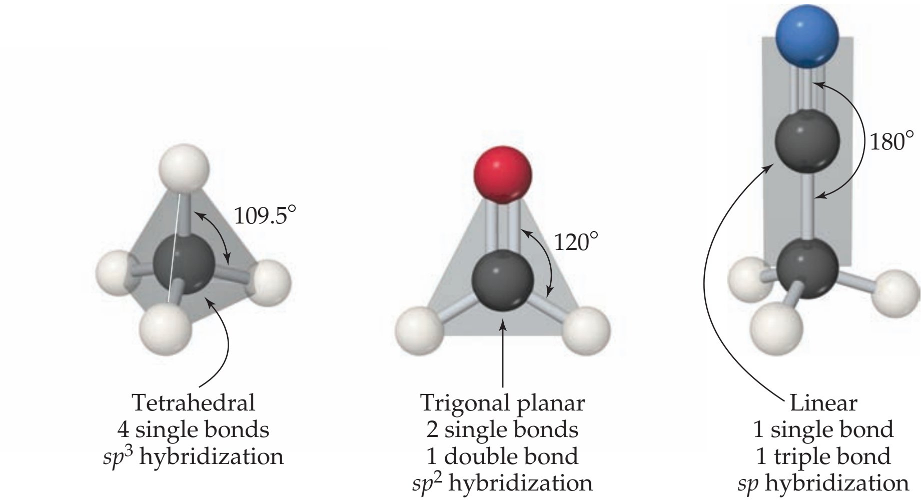
Almost every organic molecule contains C—H bonds. Because the valence shell of H can hold only two electrons, hydrogen forms only one covalent bond. As a result, hydrogen atoms are always located on the *surface* of organic molecules whereas the C—C bonds form the *backbone*, or *skeleton*, of the molecule, as in the propane molecule:



$$\mathrm{H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-H}$$

GO FIGURE

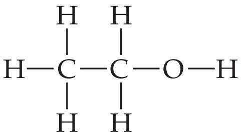
What is the geometry around the bottom carbon atom in acetonitrile?



▲ **Figure 24.1 Carbon geometries.** The three common geometries around carbon are tetrahedral as in methane (CH_4), trigonal planar as in formaldehyde (CH_2O), and linear as in acetonitrile (CH_3CN). Notice that in all cases each carbon atom forms four bonds.

The Stabilities of Organic Substances

Carbon forms strong bonds with a variety of elements, especially H, O, N, and the halogens. ∞ (Section 8.8) Carbon also has an exceptional ability to bond to itself, forming a variety of molecules made up of chains or rings of carbon atoms. Most reactions with low or moderate activation energy ∞ (Section 14.5) begin when a region of high electron density on one molecule encounters a region of low electron density on another molecule. The regions of high electron density may be due to the presence of a multiple bond or to the more electronegative atom in a polar bond. Because of their strength (the C—C single bond enthalpy is 348 kJ/mol, the C—H bond enthalpy is 413 kJ/mol ∞ Table 8.4) and lack of polarity, both C—C single bonds and C—H bonds are relatively unreactive. To better understand the implications of these facts, consider ethanol:



$$\begin{array}{ccccccc} & & H & & H & & \\ & & | & & | & & \\ H & - & C & - & C & - & O-H \\ & & | & & | & & \\ & & H & & H & & \end{array}$$

The differences in the electronegativity values of C (2.5) and O (3.5) and of O and H (2.1) indicate that the C—O and O—H bonds are quite polar. Thus, many reactions of ethanol involve these bonds while the hydrocarbon portion of the molecule remains intact. A group of atoms such as the C—O—H group, which determines how an organic molecule reacts (in other words, how the molecule *functions*), is called a **functional group**. The functional group is the center of reactivity in an organic molecule.

Give It Some Thought

Which bond is most likely to be the location of a chemical reaction: C═N, C—C, or C—H?

Solubility and Acid–Base Properties of Organic Substances

In most organic substances, the most prevalent bonds are carbon–carbon and carbon–hydrogen, which are not polar. For this reason, the overall polarity of organic molecules is often low, which makes them generally soluble in nonpolar solvents and not very soluble in water. ∞ (Section 13.3) Organic molecules that are soluble in polar solvents are those that have polar groups on the molecule surface, such as glucose and ascorbic acid (▶ **Figure 24.2**). Organic molecules that have a long, nonpolar part bonded to a polar, ionic part, such as the stearate ion shown in Figure 24.2, function as *surfactants* and are used in soaps and detergents. ∞ (Section 13.6) The nonpolar part of the molecule extends into a nonpolar medium such as grease or oil, and the polar part extends into a polar medium such as water.

Many organic substances contain acidic or basic groups. The most important acidic organic substances are the carboxylic acids, which bear the functional group —COOH. ∞ (Sections 4.3 and 16.10) The most important basic organic substances are amines, which bear the $-NH_2$, —NHR, or $-NR_2$ groups, where R is an organic group made up of carbon and hydrogen atoms. ∞ (Section 16.7)

As you read this chapter, you will find many concept links (∞) to related materials in earlier chapters. *We strongly encourage you to follow these links and review the earlier material.* Doing so will enhance your understanding and appreciation of organic chemistry and biochemistry.

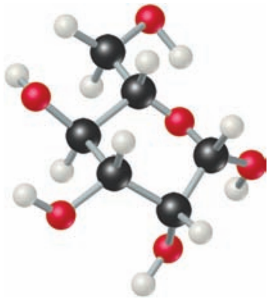
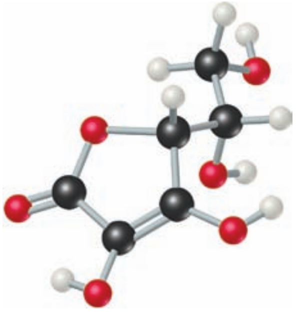
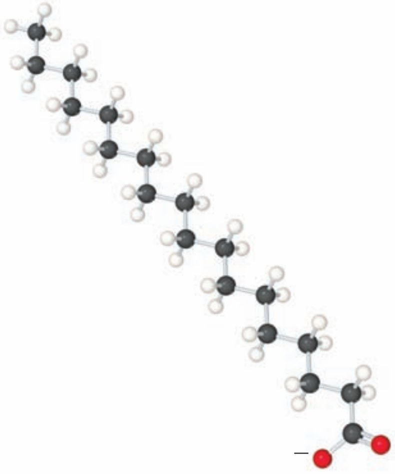
How would replacing OH groups on ascorbic acid with CH_3 groups affect the substance's solubility in (**a**) polar solvents and (**b**) nonpolar solvents?



Glucose ($C_6H_{12}O_6$)



Ascorbic acid ($HC_6H_7O_6$)



Stearate ($C_{17}H_{35}COO^-$)

▲ **Figure 24.2 Organic molecules that are soluble in polar solvents.**

24.2 | Introduction to Hydrocarbons

Because carbon compounds are so numerous, it is convenient to organize them into families that have structural similarities. The simplest class of organic compounds is the *hydrocarbons*, compounds composed of only carbon and hydrogen. The key structural feature of hydrocarbons (and of most other organic substances) is the presence of stable carbon–carbon bonds. Carbon is the only element capable of forming stable, extended chains of atoms bonded through single, double, or triple bonds.

Hydrocarbons can be divided into four types, depending on the kinds of carbon–carbon bonds in their molecules. ▼ **Table 24.1** shows an example of each type.

Alkanes contain only single $C-C$ bonds. **Alkenes**, also known as *olefins*, contain at least one $C{=}C$ double bond, and **alkynes** contain at least one $C{\equiv}C$ triple bond. In **aromatic hydrocarbons** the carbon atoms are connected in a planar ring structure, joined by both σ and delocalized π bonds between carbon atoms. (Section 8.6) Benzene (C_6H_6) is the best-known example of an aromatic hydrocarbon.

Each type of hydrocarbon exhibits different chemical behaviors, as we will see shortly. The physical properties of all four types, however, are similar in many ways. Because hydrocarbon molecules are relatively nonpolar, they are almost completely insoluble in water but dissolve readily in nonpolar solvents. Their melting points and boiling points are determined by dispersion forces. (Section 11.2) As a result, hydrocarbons of very low molecular weight, such as C_2H_6($\text{bp} = -89\ ^\circ\text{C}$), are gases at room temperature; those of moderate molecular weight, such as C_6H_{14}($\text{bp} = 69\ ^\circ\text{C}$), are liquids; and those of high molecular weight, such as $C_{22}H_{46}$($\text{mp} = 44\ ^\circ\text{C}$), are solids.

▶ **Table 24.2** lists the ten simplest alkanes. Many of these substances are familiar because they are used so widely. Methane is a major component of natural gas. Propane is the major component of bottled gas used for home heating and cooking in areas where natural gas is not available. Butane is used in disposable lighters and in fuel canisters for gas camping stoves and lanterns. Alkanes with 5 to 12 carbon atoms per molecule are used to make gasoline. Notice that each succeeding compound in Table 24.2 has an additional CH_2 unit.

Table 24.1 The Four Hydrocarbon Types with Molecular Examples

Type	Example			
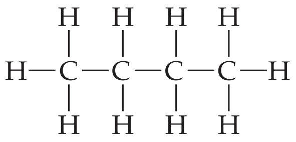
Alkane	Ethane	CH_3CH_3		Alkene	Ethylene	$CH_2{=}CH_2$		Alkyne	Acetylene	$CH{\equiv}CH$		Aromatic	Benzene	C_6H_6		 H H C C H—C 120° C—H C C 1.39 Å H H

Table 24.2 First Ten Members of the Straight-Chain Alkane Series

Molecular Formula	Condensed Structural Formula	Name	Boiling Point (°C)
CH_4	CH_4	Methane	−161
C_2H_6	CH_3CH_3	Ethane	−89
C_3H_8	$CH_3CH_2CH_3$	Propane	−44
C_4H_{10}	$CH_3CH_2CH_2CH_3$	Butane	−0.5
C_5H_{12}	$CH_3CH_2CH_2CH_2CH_3$	Pentane	36
C_6H_{14}	$CH_3CH_2CH_2CH_2CH_2CH_3$	Hexane	68
C_7H_{16}	$CH_3CH_2CH_2CH_2CH_2CH_2CH_3$	Heptane	98
C_8H_{18}	$CH_3CH_2CH_2CH_2CH_2CH_2CH_2CH_3$	Octane	125
C_9H_{20}	$CH_3CH_2CH_2CH_2CH_2CH_2CH_2CH_2CH_3$	Nonane	151
$C_{10}H_{22}$	$CH_3CH_2CH_2CH_2CH_2CH_2CH_2CH_2CH_2CH_3$	Decane	174

The formulas for the alkanes given in Table 24.2 are written in a notation called *condensed structural formulas*. This notation reveals the way in which atoms are bonded to one another but does not require drawing in all the bonds. For example, the structural formula and the condensed structural formulas for butane (C_4H_{10}) are

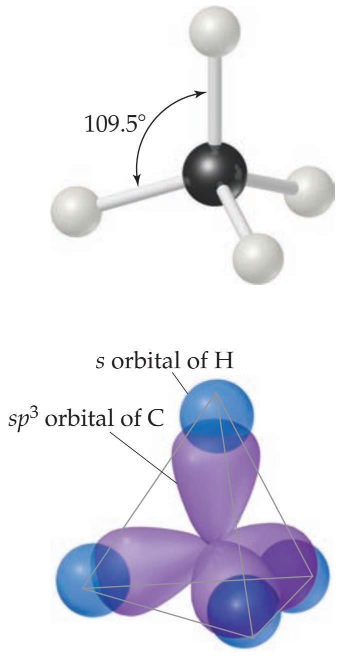


$$\begin{array}{ccccccccc} & & H & & H & & H & & H & \\ & & | & & | & & | & & | & \\ H & - & C & - & C & - & C & - & C & - & H \\ & & | & & | & & | & & | & \\ & & H & & H & & H & & H & \end{array}$$

$$H_3C—CH_2—CH_2—CH_3$$

or

$$CH_3CH_2CH_2CH_3$$



▲ **Figure 24.3 Bonds about carbon in methane.** This tetrahedral molecular geometry is found around all carbons in alkanes.

Give It Some Thought

How many C—H and C—C bonds are formed by the middle carbon atom of propane?

Structures of Alkanes

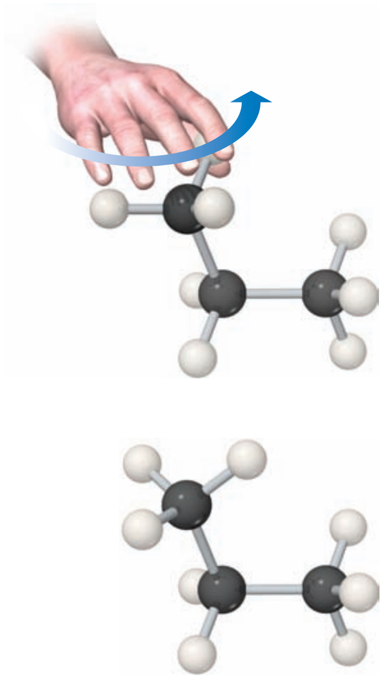
According to the VSEPR model, the molecular geometry about each carbon atom in an alkane is tetrahedral. ∞ (Section 9.2) The bonding may be described as involving sp^3-hybridized orbitals on the carbon, as pictured in ▶ **Figure 24.3** for methane. ∞ (Section 9.5)

Rotation about a carbon–carbon single bond is relatively easy and occurs rapidly at room temperature. To visualize such rotation, imagine grasping either methyl group of the propane molecule in ▶ **Figure 24.4** and rotating the group relative to the rest of the molecule. Because motion of this sort occurs rapidly in alkanes, a long-chain alkane molecule is constantly undergoing motions that cause it to change its shape, something like a length of chain that is being shaken.

Structural Isomers

The alkanes in Table 24.2 are called *straight-chain* or *linear hydrocarbons* because all the carbon atoms are joined in a continuous chain. Alkanes consisting of four or more carbon atoms can also form *branched chains*, and when they do, they are called *branched-chain hydrocarbons*. (The branches in organic molecules are often called *side chains*.) **Table 24.3**, for example, shows all the straight-chain and branched-chain alkanes containing four and five carbon atoms.

Compounds that have the same molecular formula but different bonding arrangements (and hence different structures) are called **structural isomers**. Thus, C_4H_{10} has two structural isomers and C_5H_{12} has three. The structural isomers of a given alkane differ slightly from one another in physical properties, as the melting and boiling points in Table 24.3 indicate.



▲ **Figure 24.4 Rotation about a C—C bond occurs easily and rapidly in all alkanes.**

Table 24.3 Isomers of C_4H_{10} and C_5H_{12}

Systematic Name (Common Name)	Structural Formula	Condensed Structural Formula	Space-filling Model	Melting Point (°C)	Boiling Point (°C)
Butane (*n*-butane)		$CH_3CH_2CH_2CH_3$		−138	−0.5
2-Methylpropane (isobutane)		 $CH_3-\underset{CH_3}{CH}-CH_3$		−159	−12
Pentane (*n*-pentane)		$CH_3CH_2CH_2CH_2CH_3$		−130	+36
2-Methylbutane (isopentane)		 $CH_3-\overset{CH_3}{CH}-CH_2-CH_3$		−160	+28
2,2-Dimethylpropane (neopentane)		 $CH_3-\overset{CH_3}{\underset{CH_3}{C}}-CH_3$		−16	+9

The number of possible structural isomers increases rapidly with the number of carbon atoms in the alkane. There are 18 isomers with the molecular formula C_8H_{18}, for example, and 75 with the molecular formula $C_{10}H_{22}$.

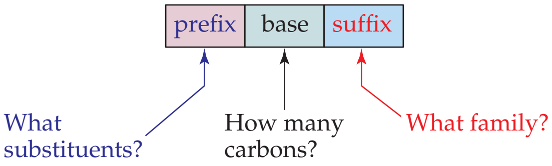
Give It Some Thought

What evidence can you cite to support the fact that although isomers have the same molecular formula they are in fact different compounds?

Nomenclature of Alkanes

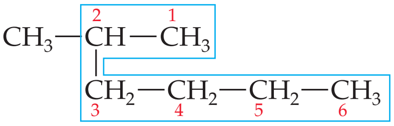
In the first column of Table 24.3, the names in parentheses are called the *common names*. The common name of the isomer with no branches begins with the letter *n* (indicating the "normal" structure). When one CH_3 group branches off the major chain, the common name of the isomer begins with *iso-*, and when two CH_3 groups branch off, the common name begins with *neo-*. As the number of isomers grows, however, it becomes impossible to find a suitable prefix to denote each isomer by a common name. The need for a systematic means of naming organic compounds was recognized as early as 1892, when an organization called the International Union of Chemistry met in Geneva to formulate rules for naming organic substances. Since that time the task of updating the rules for naming compounds has fallen to the International Union of Pure and Applied Chemistry (IUPAC). Chemists everywhere, regardless of their nationality, subscribe to a common system for naming compounds.

The IUPAC names for the isomers of butane and pentane are the ones given first in Table 24.3. These systematic names, as well as those of other organic compounds, have three parts to them:



The following steps summarize the procedures used to name alkanes, which all have names ending with *-ane*. We use a similar approach to write the names of other organic compounds.

1. **Find the longest continuous chain of carbon atoms, and use the name of this chain (given in Table 24.2) as the base name.** Be careful in this step because the longest chain may not be written in a straight line, as in the following structure:



2-Methyl*hexane*

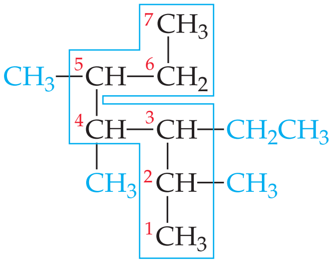
Because the longest continuous chain contains six C atoms, this isomer is named as a substituted hexane. Groups attached to the main chain are called *substituents* because they are substituted in place of an H atom on the main chain. In this molecule, the CH_3 group not enclosed by the blue outline is the only substituent in the molecule.

2. **Number the carbon atoms in the longest chain, beginning with the end nearest a substituent.** In our example, we number the C atoms beginning at the upper right because that places the CH_3 substituent on C2 of the chain. (If we had numbered from the lower right, the CH_3 would be on C5.) The chain is numbered from the end that gives the lower number to the substituent position.

3. **Name each substituent.** A substituent formed by removing an H atom from an alkane is called an **alkyl group**. Alkyl groups are named by replacing the *-ane* ending of the alkane name with *-yl*. The methyl group (CH_3), for example, is derived from methane (CH_4) and the ethyl group (C_2H_5) is derived from ethane (C_2H_6). ▶ Table 24.4 lists six common alkyl groups.

4. **Begin the name with the number or numbers of the carbon or carbons to which each substituent is bonded.** For our compound, the name 2-methylhexane indicates the presence of a methyl group on C2 of a hexane (six-carbon) chain.

5. **When two or more substituents are present, list them in alphabetical order.** The presence of two or more of the same substituent is indicated by the prefixes *di-* (two), *tri-* (three), *tetra-* (four), *penta-* (five), and so forth. The prefixes are ignored in determining the alphabetical order of the substituents:



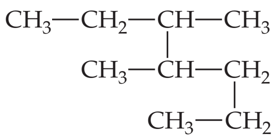
3-Ethyl-2,4,5-trimethylheptane

Table 24.4 Condensed Structural Formulas and Common Names for Several Alkyl Groups

Group	Name
CH_3-	Methyl
CH_3CH_2-	Ethyl
$CH_3CH_2CH_2-$	Propyl
$CH_3CH_2CH_2CH_2-$	Butyl
	Isopropyl
	*tert*-Butyl

SAMPLE EXERCISE 24.1 Naming Alkanes

Give the systematic name for the following alkane:



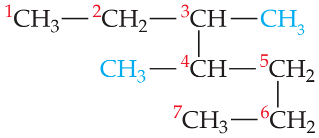
$$\begin{array}{ccccccc}
\mathrm{CH_3} & - & \mathrm{CH_2} & - & \mathrm{CH} & - & \mathrm{CH_3}\\
 & & & & | & & \\
 & & \mathrm{CH_3} & - & \mathrm{CH} & - & \mathrm{CH_2}\\
 & & & & & & | \\
 & & & & \mathrm{CH_3} & - & \mathrm{CH_2}
\end{array}$$

SOLUTION

Analyze We are given the condensed structural formula of an alkane and asked to give its name.

Plan Because the hydrocarbon is an alkane, its name ends in *-ane*. The name of the parent hydrocarbon is based on the longest continuous chain of carbon atoms. Branches are alkyl groups, named after the number of C atoms in the branch and located by counting C atoms along the longest continuous chain.

Solve The longest continuous chain of C atoms extends from the upper left CH_3 group to the lower left CH_3 group and is seven C atoms long:

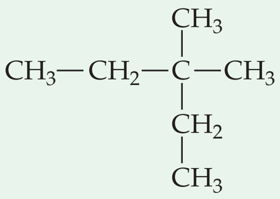


$$\begin{array}{ccccccc}
{}^{1}\mathrm{CH_3} & - & {}^{2}\mathrm{CH_2} & - & {}^{3}\mathrm{CH} & - & \mathrm{CH_3}\\
 & & & & | & & \\
 & & \mathrm{CH_3} & - & {}^{4}\mathrm{CH} & - & {}^{5}\mathrm{CH_2}\\
 & & & & & & | \\
 & & & & {}^{7}\mathrm{CH_3} & - & {}^{6}\mathrm{CH_2}
\end{array}$$

The parent compound is thus heptane. There are two methyl groups branching off the main chain. Hence, this compound is a dimethylheptane. To specify the location of the two methyl groups, we must number the C atoms from the end that gives the lower two numbers to the carbons bearing side chains. This means that we should start numbering at the upper left carbon. There is a methyl group on C3 and one on C4. The compound is thus 3,4-dimethylheptane.

Practice Exercise 1

What is the proper name of this compound?

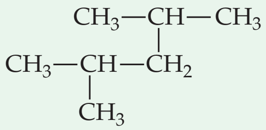


$$\begin{array}{ccccccc}
 & & & & \mathrm{CH_3} & & \\
 & & & & | & & \\
\mathrm{CH_3} & - & \mathrm{CH_2} & - & \mathrm{C} & - & \mathrm{CH_3}\\
 & & & & | & & \\
 & & & & \mathrm{CH_2} & & \\
 & & & & | & & \\
 & & & & \mathrm{CH_3} & &
\end{array}$$

(a) 3-ethyl-3-methylbutane, **(b)** 2-ethyl-2-methylbutane,
(c) 3,3-dimethylpentane, **(d)** isoheptane,
(e) 1,2-dimethyl-neopentane.

Practice Exercise 2

Name the following alkane:



$$\begin{array}{ccccccc}
 & & \mathrm{CH_3} & - & \mathrm{CH} & - & \mathrm{CH_3}\\
 & & & & | & & \\
\mathrm{CH_3} & - & \mathrm{CH} & - & \mathrm{CH_2} & & \\
 & & | & & & & \\
 & & \mathrm{CH_3} & & & &
\end{array}$$

SAMPLE EXERCISE 24.2 Writing Condensed Structural Formulas

Write the condensed structural formula for 3-ethyl-2-methylpentane.

SOLUTION

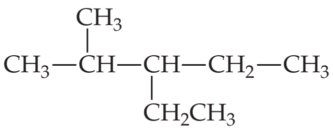
Analyze We are given the systematic name for a hydrocarbon and asked to write its condensed structural formula.

Plan Because the name ends in *-ane*, the compound is an alkane, meaning that all the carbon–carbon bonds are single bonds. The parent hydrocarbon is pentane, indicating five C atoms (Table 24.2). There are two alkyl groups specified, an ethyl group (two carbon atoms, C_2H_5) and a methyl group (one carbon atom, CH_3). Counting from left to right along the five-carbon chain, the name tells us that the ethyl group is attached to C3 and the methyl group is attached to C2.

Solve We begin by writing five C atoms attached by single bonds. These represent the backbone of the parent pentane chain:

$$\mathrm{C{-}C{-}C{-}C{-}C}$$

We next place a methyl group on the second C and an ethyl group on the third C of the chain. We then add hydrogens to all the other C atoms to make four bonds to each carbon:



$$\begin{array}{ccccccccc}
 & & \mathrm{CH_3} & & & & & & \\
 & & | & & & & & & \\
\mathrm{CH_3} & - & \mathrm{CH} & - & \mathrm{CH} & - & \mathrm{CH_2} & - & \mathrm{CH_3}\\
 & & & & | & & & & \\
 & & & & \mathrm{CH_2CH_3} & & & &
\end{array}$$

The formula can be written more concisely as

$$\mathrm{CH_3CH(CH_3)CH(C_2H_5)CH_2CH_3}$$

where the branching alkyl groups are indicated in parentheses.

Practice Exercise 1

How many hydrogen atoms are in 2,2-dimethylhexane?
(a) 6, **(b)** 8, **(c)** 16, **(d)** 18, **(e)** 20.

Practice Exercise 2

Write the condensed structural formula for 2,3-dimethylhexane.

Cycloalkanes

Alkanes that form rings, or cycles, are called **cycloalkanes**. As ▼ **Figure 24.5** illustrates, cycloalkane structures are sometimes drawn as *line structures*, which are polygons in which each corner represents a CH_2 group. This method of representation is similar to that used for benzene rings. (Section 8.6) (Remember from our benzene discussion that in aromatic structures each vertex represents a CH group, not a CH_2 group.)

Carbon rings containing fewer than five carbon atoms are strained because the C—C—C bond angles must be less than the 109.5° tetrahedral angle. The amount of strain increases as the rings get smaller. In cyclopropane, which has the shape of an equilateral triangle, the angle is only 60°; this molecule is therefore much more reactive than propane, its straight-chain analog.

Give It Some Thought

Are the C—C bonds cyclopropane weaker than those in cyclohexane?

Reactions of Alkanes

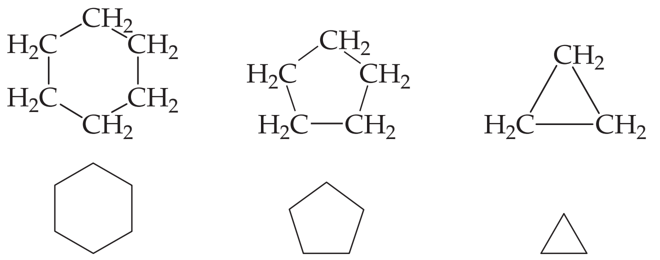
Because they contain only C—C and C—H bonds, most alkanes are relatively unreactive. At room temperature, for example, they do not react with acids, bases, or strong oxidizing agents. Their low chemical reactivity, as noted in Section 24.1, is due primarily to the strength and lack of polarity of C—C and C—H bonds.

Alkanes are not completely inert, however. One of their most commercially important reactions is *combustion* in air, which is the basis of their use as fuels. (Section 3.2) For example, the complete combustion of ethane proceeds according to this highly exothermic reaction:

$$2\,C_2H_6(g) + 7\,O_2(g) \longrightarrow 4\,CO_2(g) + 6\,H_2O(l) \qquad \Delta H^\circ = -2855\text{ kJ}$$

GO FIGURE

The general formula for straight-chain alkanes is C_nH_{2n+2}. What is the general formula for cycloalkanes?



Cyclohexane

Each vertex represents one CH_2 group

Cyclopentane

Five vertices = five CH_2 groups

Cyclopropane

Three vertices = three CH_2 groups

▲ **Figure 24.5** **Condensed structural formulas and line structures for three cycloalkanes.**

Chemistry Put to Work

Gasoline

Petroleum, or crude oil, is a mixture of hydrocarbons plus smaller quantities of other organic compounds containing nitrogen, oxygen, or sulfur. The tremendous demand for petroleum to meet the world's energy needs has led to the tapping of oil wells in such forbidding places as the North Sea and northern Alaska.

The usual first step in the *refining*, or processing, of petroleum is to separate it into fractions on the basis of boiling point (▼ **Table 24.5**). Because gasoline is the most commercially important of these fractions, various processes are used to maximize its yield.

Gasoline is a mixture of volatile alkanes and aromatic hydrocarbons. In a traditional automobile engine, a mixture of air and gasoline vapor is compressed by a piston and then ignited by a spark plug. The burning of the gasoline should create a strong, smooth expansion of gas, forcing the piston outward and imparting force along the driveshaft of the engine. If the gas burns too rapidly, the piston receives a single hard slam rather than a strong, smooth push. The result is a "knocking" or "pinging" sound and a reduction in the efficiency with which energy produced by the combustion is converted to work.

▲ **Figure 24.6 Octane rating.** The octane rating of gasoline measures its resistance to knocking when burned in an engine. The octane rating of the gasoline in the foreground is 89.

The *octane number* of a gasoline is a measure of its resistance to knocking. Gasolines with high octane numbers burn more smoothly and are thus more effective fuels (▶ **Figure 24.6**). Branched alkanes and aromatic hydrocarbons have higher octane numbers than straight-chain alkanes. The octane number of gasoline is obtained by comparing its knocking characteristics with those of isooctane (2,2,4-trimethylpentane) and heptane. Isooctane is assigned an octane number of 100, and heptane is assigned 0. Gasoline with the same knocking characteristics as a mixture of 91% isooctane and 9% heptane, for instance, is rated as 91 octane.

Table 24.5 Hydrocarbon Fractions from Petroleum

Fraction	Size Range of Molecules	Boiling-Point Range (°C)	Uses
Gas	C_1 to C_5	−160 to 30	Gaseous fuel, production of H_2
Straight-run gasoline	C_5 to C_{12}	30 to 200	Motor fuel
Kerosene, fuel oil	C_{12} to C_{18}	180 to 400	Diesel fuel, furnace fuel, cracking
Lubricants	C_{16} and up	350 and up	Lubricants
Paraffins	C_{20} and up	Low-melting solids	Candles, matches
Asphalt	C_{36} and up	Gummy residues	Surfacing roads

The gasoline obtained by fractionating petroleum (called *straight-run* gasoline) contains mainly straight-chain hydrocarbons and has an octane number around 50. To increase its octane rating, it is subjected to a process called *reforming*, which converts the straight-chain alkanes into branched-chain ones.

Cracking is used to produce aromatic hydrocarbons and to convert some of the less-volatile fractions of petroleum into compounds suitable for use as automobile fuel. In cracking, the hydrocarbons are mixed with a catalyst and heated to 400–500 °C. The catalysts used are either clay minerals or synthetic Al_2O_3–SiO_2 mixtures. In addition to forming molecules more suitable for gasoline, cracking results in the formation of such low-molecular-weight hydrocarbons as ethylene and propene. These substances are used in a variety of reactions to form plastics and other chemicals.

Adding compounds called either *antiknock agents* or octane enhancers increases the octane rating of gasoline. Until the mid-1970s the principal antiknock agent was tetraethyl lead, $(C_2H_5)_4Pb$. It is no longer used, however, because of the environmental hazards of lead and because it poisons catalytic converters. ∞ (Section 14.7, "Catalytic Converters") Aromatic compounds such as toluene $(C_6H_5CH_3)$ and oxygenated hydrocarbons such as ethanol (CH_3CH_2OH) are now generally used as antiknock agents.

24.3 | Alkenes, Alkynes, and Aromatic Hydrocarbons

Because alkanes have only single bonds, they contain the largest possible number of hydrogen atoms per carbon atom. As a result, they are called *saturated hydrocarbons*. Alkenes, alkynes, and aromatic hydrocarbons contain multiple carbon–carbon bonds (double,

triple, or delocalized π bonds). As a result, they contain less hydrogen than an alkane with the same number of carbon atoms. Collectively, they are called *unsaturated hydrocarbons*. On the whole, unsaturated molecules are more reactive than saturated ones.

Alkenes

Alkenes are unsaturated hydrocarbons that contain at least one $C{=}C$ bond. The simplest alkene is $CH_2{=}CH_2$, called ethene (IUPAC) or ethylene (common name), which plays important roles as a plant hormone in seed germination and fruit ripening. The next member of the series is $CH_3{-}CH{=}CH_2$, called propene or propylene. Alkenes with four or more carbon atoms have several isomers. For example, the alkene C_4H_8 has the four structural isomers shown in ▲ **Figure 24.7**. Notice both their structures and their names.

The names of alkenes are based on the longest continuous chain of carbon atoms that contains the double bond. The chain is named by changing the ending of the name of the corresponding alkane from *-ane* to *-ene*. The compound on the left in Figure 24.7, for example, has a double bond as part of a three-carbon chain; thus, the parent alkene is propene.

The location of the double bond along an alkene chain is indicated by a prefix number that designates the double-bond carbon atom that is nearest an end of the chain. The chain is always numbered from the end that brings us to the double bond sooner and hence gives the smallest-numbered prefix. In propene, the only possible location for the double bond is between the first and second carbons; thus, a prefix indicating its location is unnecessary. For butene (Figure 24.7), there are two possible positions for the double bond, either after the first carbon (1-butene) or after the second carbon (2-butene).

Give It Some Thought

How many distinct locations are there for a double bond in a five-carbon linear chain?

If a substance contains two or more double bonds, the location of each is indicated by a numerical prefix, and the ending of the name is altered to identify the number of double bonds: diene (two), triene (three), and so forth. For example, $CH_2{=}CH{-}CH_2{-}CH{=}CH_2$ is 1,4-pentadiene.

The two isomers on the right in Figure 24.7 differ in the relative locations of their methyl groups. These two compounds are **geometric isomers**, compounds that have the same molecular formula and the same groups bonded to one another

but differ in the spatial arrangement of these groups. (Section 23.4) In the cis isomer the two methyl groups are on the same side of the double bond, whereas in the trans isomer they are on opposite sides. Geometric isomers possess distinct physical properties and can differ significantly from each other in their chemical behavior.

Geometric isomerism in alkenes arises because, unlike the C—C bond, the C═C bond resists twisting. Recall from Section 9.6 that the double bond between two carbon atoms consists of a σ and a π bond. ▲ Figure 24.8 shows a cis alkene. The carbon–carbon bond axis and the bonds to the hydrogen atoms and to the alkyl groups (designated R) are all in a plane, and the *p* orbitals that form the π bond are perpendicular to that plane. As Figure 24.8 shows, rotation around the carbon–carbon double bond requires the π bond to be broken, a process that requires considerable energy (about 250 kJ/mol). Because rotation does not occur easily around the carbon–carbon bond, the cis and trans isomers of an alkene cannot readily interconvert and, therefore, exist as distinct compounds.

SAMPLE EXERCISE 24.3 Drawing Isomers

Draw all the structural and geometric isomers of pentene, C_5H_{10}, that have an unbranched hydrocarbon chain.

SOLUTION

Analyze We are asked to draw all the isomers (both structural and geometric) for an alkene with a five-carbon chain.

Plan Because the compound is named pentene and not pentadiene or pentatriene, we know that the five-carbon chain contains only one carbon–carbon double bond. Thus, we begin by placing the double bond in various locations along the chain, remembering that the chain can be numbered from either end. After finding the different unique locations for the double bond, we consider whether the molecule can have cis and trans isomers.

Solve There can be a double bond after either the first carbon (1-pentene) or second carbon (2-pentene). These are the only two possibilities because the chain can be numbered from either end. Thus, what we might erroneously call 3-pentene is actually 2-pentene, as seen by numbering the carbon chain from the other end:

$$\overset{1}{C}=\overset{2}{C}-\overset{3}{C}-\overset{4}{C}-\overset{5}{C}$$

$$\overset{1}{C}-\overset{2}{C}=\overset{3}{C}-\overset{4}{C}-\overset{5}{C}$$

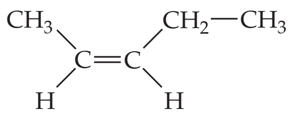
$$\overset{1}{C}-\overset{2}{C}-\overset{3}{C}=\overset{4}{C}-\overset{5}{C} \quad \text{renumbered as} \quad \overset{5}{C}-\overset{4}{C}-\overset{3}{C}=\overset{2}{C}-\overset{1}{C}$$

$$\overset{1}{C}-\overset{2}{C}-\overset{3}{C}-\overset{4}{C}=\overset{5}{C} \quad \text{renumbered as} \quad \overset{5}{C}-\overset{4}{C}-\overset{3}{C}-\overset{2}{C}=\overset{1}{C}$$

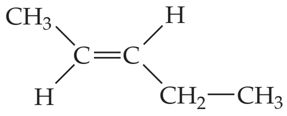
Because the first C atom in 1-pentene is bonded to two H atoms, there are no cis–trans isomers. There are cis and trans isomers for 2-pentene, however. Thus, the three isomers for pentene are

$CH_2{=}CH{-}CH_2{-}CH_2{-}CH_3$

1-Pentene



cis-2-Pentene



trans-2-Pentene

(You should convince yourself that *cis*-3-pentene is identical to *cis*-2-pentene and *trans*-3-pentene is identical to *trans*-2-pentene. However, *cis*-2-pentene and *trans*-2-pentene are the correct names because they have smaller numbered prefixes.)

Practice Exercise 1

Which compound does not exist?
(a) 1,2,3,4,5,6,7-octaheptaene, **(b)** *cis*-2-butane, **(c)** *trans*-3-hexene,
(d) 1-propene, **(e)** *cis*-4-decene.

Practice Exercise 2

How many straight-chain isomers are there of hexene, C_6H_{12}?

Alkynes

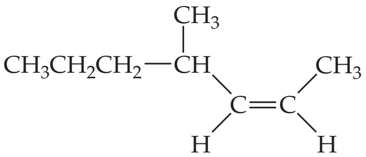
Alkynes are unsaturated hydrocarbons containing one or more $C{\equiv}C$ bonds. The simplest alkyne is acetylene (C_2H_2), a highly reactive molecule. When acetylene is burned in a stream of oxygen in an oxyacetylene torch, the flame reaches about 3200 K. Because alkynes in general are highly reactive, they are not as widely distributed in nature as alkenes; alkynes, however, are important intermediates in many industrial processes.

Alkynes are named by identifying the longest continuous chain containing the triple bond and modifying the ending of the name of the corresponding alkane from *-ane* to *-yne*, as shown in Sample Exercise 24.4.

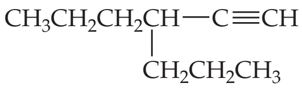
SAMPLE EXERCISE 24.4 Naming Unsaturated Hydrocarbons

Name the following compounds:

(a)



(b)



$CH_3CH_2CH_2\underset{\displaystyle CH_2CH_2CH_3}{\underset{|}{CH}}{-}C{\equiv}CH$

SOLUTION

Analyze We are given the condensed structural formulas for an alkene and an alkyne and asked to name the compounds.

Plan In each case, the name is based on the number of carbon atoms in the longest continuous carbon chain that contains the multiple bond. In the alkene, care must be taken to indicate whether cis–trans isomerism is possible and, if so, which isomer is given.

Solve

(a) The longest continuous chain of carbons that contains the double bond is seven carbons long, so the parent hydrocarbon is heptene. Because the double bond begins at carbon 2 (numbering from the end closer to the double bond), we have 2-heptene. With a methyl group at carbon atom 4, we have 4-methyl-2-heptene. The geometrical configuration at the double bond is cis (that is, the alkyl groups are bonded to the double bond on the same side). Thus, the full name is 4-methyl-*cis*-2-heptene.

(b) The longest continuous chain containing the triple bond has six carbons, so this compound is a derivative of hexyne. The triple bond comes after the first carbon (numbering from the right), making it 1-hexyne. The branch from the hexyne chain contains three carbon atoms, making it a propyl group. Because this substituent is located on C3 of the hexyne chain, the molecule is 3-propyl-1-hexyne.

Practice Exercise 1

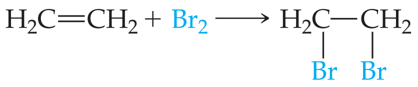
If a compound has two carbon–carbon triple bonds and one carbon–carbon double bond, what class of compound is it?
(a) an eneyne, **(b)** a dieneyne, **(c)** a trieneyne, **(d)** an enediyne, **(e)** an enetriyne.

Practice Exercise 2

Draw the condensed structural formula for 4-methyl-2-pentyne.

Addition Reactions of Alkenes and Alkynes

The presence of carbon–carbon double or triple bonds in hydrocarbons markedly increases their chemical reactivity. The most characteristic reactions of alkenes and alkynes are **addition reactions**, in which a reactant is added to the two atoms that form the multiple bond. A simple example is the addition of elemental bromine to ethylene to produce 1,2,-dibromoethane:



$$H_2C{=}CH_2 + Br_2 \longrightarrow \underset{\displaystyle Br}{\underset{|}{H_2C}}{-}\underset{\displaystyle Br}{\underset{|}{CH_2}} \qquad [24.1]$$

The π bond in ethylene is broken and the electrons that formed the bond are used to form two σ bonds to the two bromine atoms. The σ bond between the carbon atoms is retained.

Addition of H_2 to an alkene converts it to an alkane:

$$CH_3CH{=}CHCH_3 + H_2 \xrightarrow{\text{Ni, 500 °C}} CH_3CH_2CH_2CH_3 \qquad [24.2]$$

The reaction between an alkene and H_2, referred to as *hydrogenation*, does not occur readily at ordinary temperatures and pressures. One reason for the lack of reactivity of H_2 toward alkenes is the stability of the H_2 bond. To promote the reaction, the reaction temperature must be raised (500 °C), and a catalyst (such as Ni) is used to assist in rupturing the H—H bond. We write such conditions over the reaction arrow to indicate they must be present in order for the reaction to occur. The most widely used catalysts are finely divided metals on which H_2 is adsorbed. ∞ (Section 14.7)

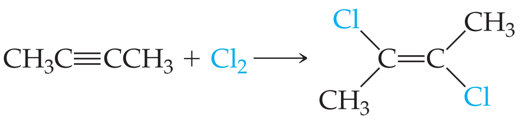
Hydrogen halides and water can also add to the double bond of alkenes, as in these reactions of ethylene:

$$CH_2{=}CH_2 + HBr \longrightarrow CH_3CH_2Br \qquad [24.3]$$

$$CH_2{=}CH_2 + H_2O \xrightarrow{H_2SO_4} CH_3CH_2OH \qquad [24.4]$$

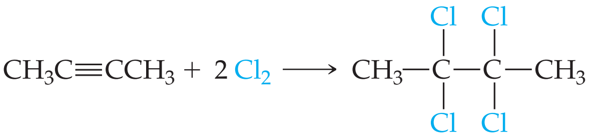
The addition of water is catalyzed by a strong acid, such as H_2SO_4.

The addition reactions of alkynes resemble those of alkenes, as shown in these examples:



[24.5]

2-Butyne *trans*-2,3-Dichloro-2-butene



$$CH_3C{\equiv}CCH_3 + 2\,Cl_2 \longrightarrow CH_3{-}\overset{\displaystyle Cl}{\overset{|}{\underset{\displaystyle Cl}{\underset{|}{C}}}}{-}\overset{\displaystyle Cl}{\overset{|}{\underset{\displaystyle Cl}{\underset{|}{C}}}}{-}CH_3 \qquad [24.6]$$

2-Butyne 2,2,3,3-Tetrachlorobutane

SAMPLE EXERCISE 24.5 Predicting the Product of an Addition Reaction

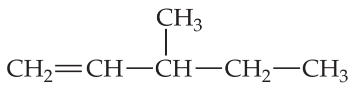
Write the condensed structural formula for the product of the hydrogenation of 3-methyl-1-pentene.

SOLUTION

Analyze We are asked to predict the compound formed when a particular alkene undergoes hydrogenation (reaction with H_2) and to write the condensed structural formula of the product.

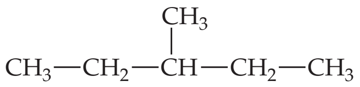
Plan To determine the condensed structural formula of the product, we must first write the condensed structural formula or Lewis structure of the reactant. In the hydrogenation of the alkene, H_2 adds to the double bond, producing an alkane.

Solve The name of the starting compound tells us that we have a chain of five C atoms with a double bond at one end (position 1) and a methyl group on C3:



$$CH_2{=}CH{-}\overset{\overset{\displaystyle CH_3}{|}}{C}H{-}CH_2{-}CH_3$$

Hydrogenation—the addition of two H atoms to the carbons of the double bond—leads to the following alkane:



$$CH_3{-}CH_2{-}\overset{\overset{\displaystyle CH_3}{|}}{C}H{-}CH_2{-}CH_3$$

Comment The longest chain in this alkane has five carbon atoms; the product is therefore 3-methylpentane.

Practice Exercise 1

What product is formed from the hydrogenation of 2-methylpropene? (**a**) propane, (**b**) butane, (**c**) 2-methylbutane, (**d**) 2-methylpropane, (**e**) 2-methylpropyne.

Practice Exercise 2

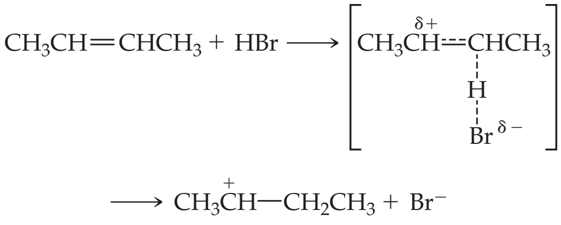
Addition of HCl to an alkene forms 2-chloropropane. What is the alkene?

A Closer Look

Mechanism of Addition Reactions

As the understanding of chemistry has grown, chemists have advanced from simply cataloging reactions that occur to explaining *how* they occur, by drawing the individual steps of a reaction based upon experimental and theoretical evidence. The sum of these steps is termed a *reaction mechanism*. (Section 14.6)

The addition reaction between HBr and an alkene, for instance, is thought to proceed in two steps. In the first step, which is rate determining (Section 14.6), HBr attacks the electron-rich double bond, transferring a proton to one of the double-bond carbons. In the reaction of 2-butene with HBr, for example, the first step is

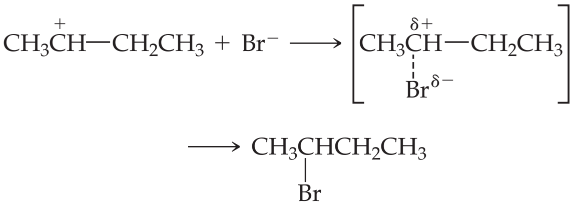


$$CH_3CH{=}CHCH_3 + HBr \longrightarrow \left[CH_3\overset{\delta+}{C}H{=\!=}\underset{\underset{\underset{\displaystyle Br^{\delta-}}{\vdots}}{\underset{\displaystyle H}{\vdots}}}{C}HCH_3 \right]$$

$$\longrightarrow CH_3\overset{+}{C}H{-}CH_2CH_3 + Br^- \qquad [24.7]$$

The electron pair that formed the π bond is used to form the new C—H bond.

The second, faster step is addition of Br^- to the positively charged carbon. The bromide ion donates a pair of electrons to the carbon, forming the C—Br bond:



$$CH_3\overset{+}{C}H{-}CH_2CH_3 + Br^- \longrightarrow \left[CH_3\underset{\underset{\displaystyle Br^{\delta-}}{\vdots}}{\overset{\delta+}{C}H}{-}CH_2CH_3 \right]$$

$$\longrightarrow CH_3\underset{\underset{\displaystyle Br}{|}}{C}HCH_2CH_3 \qquad [24.8]$$

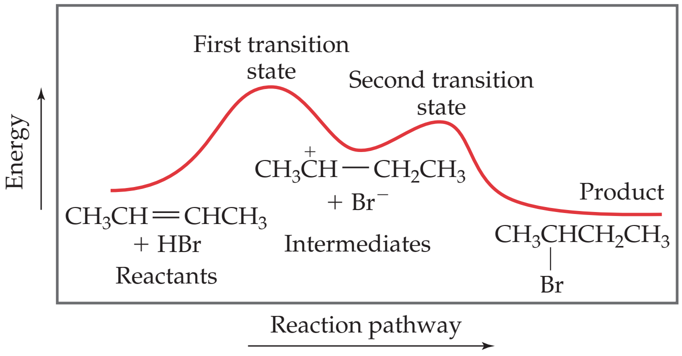
Because the rate-determining step involves both the alkene and the acid, the rate law for the reaction is second order, first order in the alkene and first order in HBr:

$$\text{Rate} = -\frac{\Delta[CH_3CH{=}CHCH_3]}{\Delta t} = k[CH_3CH{=}CHCH_3][HBr] \qquad [24.9]$$

The energy profile for the reaction is shown in **Figure 24.9**. The first energy maximum represents the transition state in the first step, and the second maximum represents the transition state in the second step. The energy minimum represents the energies of the intermediate species, $CH_3\overset{+}{C}H{-}CH_2CH_3$ and Br^-.

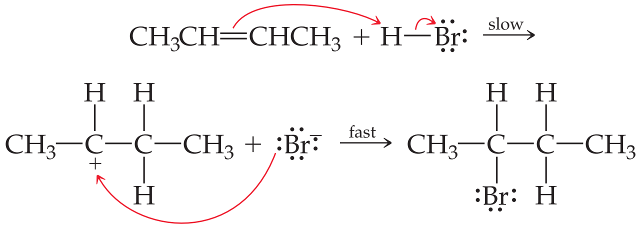
GO FIGURE

What features of an energy profile allow you to distinguish between an intermediate and a transition state?



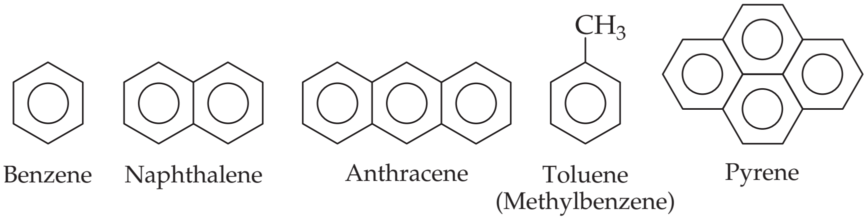
▲ **Figure 24.9** **Energy profile for addition of HBr to 2-butene.** The two maxima tell you that this is a two-step mechanism.

To show electron movement in reactions like these, chemists often use curved arrows pointing in the direction of electron flow. For the addition of HBr to 2-butene, for example, the shifts in electron positions are shown as



Aromatic Hydrocarbons

The simplest aromatic hydrocarbon, benzene (C_6H_6), is shown in ▼ **Figure 24.10** along with some other aromatic hydrocarbons. Benzene is the most important aromatic hydrocarbon, and most of our discussion focuses on it.

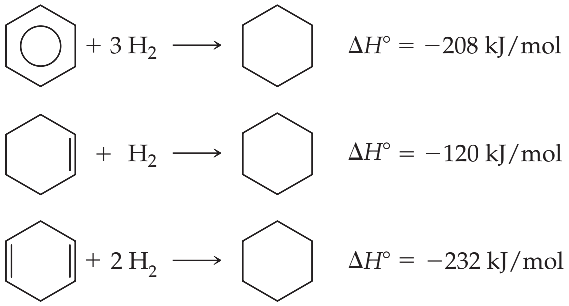


▲ **Figure 24.10** **Line formulas and common names of several aromatic compounds.** The aromatic rings are represented by hexagons with a circle inscribed inside to denote delocalized π bonds. Each vertex represents a carbon atom. Each carbon is bound to three other atoms—either three carbons, or two carbons and a hydrogen—so that each carbon has the requisite four bonds.

Stabilization of π Electrons by Delocalization

If you draw one Lewis structure for benzene, you draw a ring that contains three CC double bonds and three single CC bonds. ∞ (Section 8.6) You might therefore expect benzene to resemble the alkenes and to be highly reactive. Benzene and the other aromatic hydrocarbons, however, are much more stable than alkenes because the π electrons are delocalized in the π orbitals. ∞ (Section 9.6)

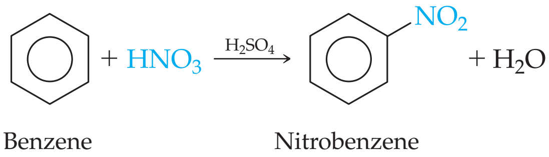
We can estimate the stabilization of the π electrons in benzene by comparing the energy required to form cyclohexane by adding hydrogen to benzene, to cyclohexene (one double bond) and to 1,4-cyclohexadiene (two double bonds):



From the second and third reactions, it appears that the energy required to hydrogenate each double bond is roughly 118 kJ/mol for each bond. Benzene contains the equivalent of three double bonds. We might expect, therefore, the energy required to hydrogenate benzene to be about 3 times −118, or −354 kJ/mol, if benzene behaved as though it were “cyclohexatriene,” that is, if it behaved as though it had three isolated double bonds in a ring. Instead, the energy released is 146 kJ less than this, indicating that benzene is more stable than would be expected for three double bonds. The difference of 146 kJ/mol between the expected heat of hydrogenation (−354 kJ/mol) and the observed heat of hydrogenation, (−208 kJ/mol) is due to stabilization of the π electrons through delocalization in the π orbitals that extend around the ring. Chemists call this stabilization energy the *resonance energy*.

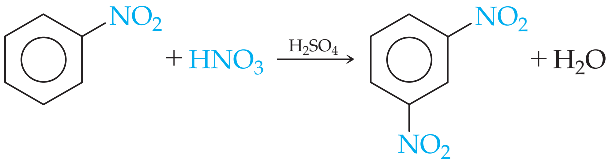
Substitution Reactions

Although aromatic hydrocarbons are unsaturated, *they do not readily undergo addition reactions*. The delocalized π bonding causes aromatic compounds to behave quite differently from alkenes and alkynes. Benzene, for example, does not add Cl_2 or Br_2 to its double bonds under ordinary conditions. In contrast, aromatic hydrocarbons undergo **substitution reactions** relatively easily. In a substitution reaction, one hydrogen atom of the molecule is removed and replaced (substituted) by another atom or group of atoms. When benzene is warmed in a mixture of nitric and sulfuric acids, for example, one of the benzene hydrogens is replaced by the nitro group, NO_2:



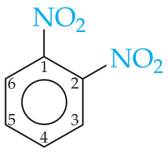
[24.10]

More vigorous treatment results in substitution of a second nitro group into the molecule:

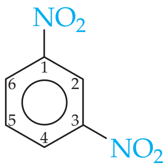


[24.11]

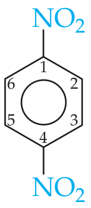
There are three isomers of benzene that contain two nitro groups—the 1,2- or *ortho*- isomer, the 1,3- or *meta*-isomer, and the 1,4- or *para*-isomer of dinitrobenzene:



ortho-Dinitrobenzene
1,2-Dinitrobenzene
mp 118 °C



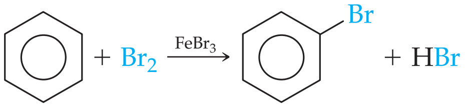
meta-Dinitrobenzene
1,3-Dinitrobenzene
mp 90 °C



para-Dinitrobenzene
1,4-Dinitrobenzene
mp 174 °C

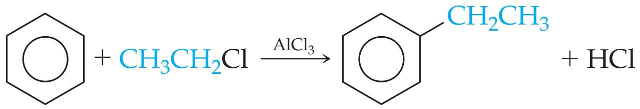
In the reaction of Equation 24.11, the principal product is the *meta* isomer.

Bromination of benzene, carried out with $FeBr_3$ as a catalyst, is another substitution reaction:



[24.12]

In a similar substitution reaction, called the *Friedel–Crafts reaction*, alkyl groups can be substituted onto an aromatic ring by reacting an alkyl halide with an aromatic compound in the presence of $AlCl_3$ as a catalyst:



[24.13]

Give It Some Thought

When the aromatic hydrocarbon naphthalene, shown in Figure 24.10, reacts with nitric and sulfuric acids, two compounds containing one nitro group are formed. Draw the structures of these two compounds.

24.4 | Organic Functional Groups

The C=C double bonds of alkenes and C≡C triple bonds of alkynes are just two of many functional groups in organic molecules. As noted earlier, these functional groups each undergo characteristic reactions, and the same is true of all other functional groups. Each kind of functional group often undergoes the same kinds of reactions in every molecule, regardless of the size and complexity of the molecule. Thus, the chemistry of an organic molecule is largely determined by the functional groups it contains.

▶ **Table 24.6** lists the most common functional groups. Notice that, except for C=C and C≡C, they all contain either O, N, or a halogen atom, X.

We can think of organic molecules as being composed of functional groups bonded to one or more alkyl groups. The alkyl groups, which are made of C—C and C—H single bonds, are the less reactive portions of the molecules. In describing general features of organic compounds, chemists often use the designation R to represent any alkyl group: methyl, ethyl, propyl, and so on. Alkanes, for example, which contain no functional group, are represented as R—H. Alcohols, which contain the functional group —OH, are represented as R—OH. If two or more different alkyl groups are present in a molecule, we designate them R, R′, R″, and so forth.

Alcohols

Alcohols are compounds in which one or more hydrogens of a parent hydrocarbon have been replaced by the functional group —OH, called either the

hydroxyl group or the *alcohol group*. Note in ▲ **Figure 24.11** that the name for an alcohol ends in *-ol*. The simple alcohols are named by changing the last letter in the name of the corresponding alkane to *-ol*—for example, ethan*e* becomes ethan*ol*. Where necessary, the location of the OH group is designated by a numeric prefix that indicates the number of the carbon atom bearing the OH group.

The O—H bond is polar, so alcohols are more soluble in polar solvents than are hydrocarbons. The —OH functional group can also participate in hydrogen bonding. As a result, the boiling points of alcohols are higher than those of their parent alkanes.

Anti-Freeze Coolant
Windshield Washer Fluid
After Shave
Isopropyl Alcohol
Nite Time

▲ **Figure 24.12** **Everyday alcohols.** Many of the products we use every day—from rubbing alcohol to hair spray and antifreeze—are composed either entirely or mainly of alcohols.

◀ **Figure 24.12** shows several commercial products that consist entirely or in large part of an alcohol.

The simplest alcohol, methanol (methyl alcohol), has many industrial uses and is produced on a large scale by heating carbon monoxide and hydrogen under pressure in the presence of a metal oxide catalyst:

$$\mathrm{CO}(g) + 2\,\mathrm{H_2}(g) \xrightarrow[400\,^\circ\mathrm{C}]{200-300\text{ atm}} \mathrm{CH_3OH}(g) \qquad [24.14]$$

Because methanol has a very high octane rating as an automobile fuel, it is used as a gasoline additive and as a fuel in its own right.

Ethanol (ethyl alcohol, C_2H_5OH) is a product of the fermentation of carbohydrates such as sugars and starches. In the absence of air, yeast cells convert these carbohydrates into ethanol and CO_2:

$$\mathrm{C_6H_{12}O_6}(aq) \xrightarrow{\text{yeast}} 2\,\mathrm{C_2H_5OH}(aq) + 2\,\mathrm{CO_2}(g) \qquad [24.15]$$

In the process, the yeast cells derive energy necessary for growth. This reaction is carried out under carefully controlled conditions to produce beer, wine, and other beverages in which ethanol (called just "alcohol" in everyday language) is the active ingredient.

The simplest polyhydroxyl alcohol (an alcohol containing more than one OH group) is 1,2-ethanediol (ethylene glycol, $HOCH_2CH_2OH$), the major ingredient in automobile antifreeze. Another common polyhydroxyl alcohol is 1,2,3-propanetriol (glycerol, $HOCH_2CH(OH)CH_2OH$), a viscous liquid that dissolves readily in water and is used in cosmetics as a skin softener and in foods and candies to keep them moist.

Phenol is the simplest compound with an OH group attached to an aromatic ring. One of the most striking effects of the aromatic group is the greatly increased acidity of the OH group. Phenol is about 1 million times more acidic in water than a nonaromatic alcohol. Even so, it is not a very strong acid ($K_a = 1.3 \times 10^{-10}$). Phenol is used industrially to make plastics and dyes, and as a topical anesthetic in throat sprays.

Cholesterol, shown in Figure 24.11, is a biochemically important alcohol. The OH group forms only a small component of this molecule, so cholesterol is only slightly soluble in water (2.6 g/L of H_2O). Cholesterol is a normal and essential component of our bodies; when present in excessive amounts, however, it may precipitate from solution. It precipitates in the gallbladder to form crystalline lumps called *gallstones*. It may also precipitate against the walls of veins and arteries and thus contribute to high blood pressure and other cardiovascular problems.

Ethers

Compounds in which two hydrocarbon groups are bonded to one oxygen are called **ethers**. Ethers can be formed from two molecules of alcohol by eliminating a molecule of water. The reaction is catalyzed by sulfuric acid, which takes up water to remove it from the system:

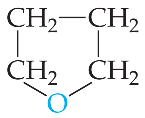
$$CH_3CH_2-OH + H-OCH_2CH_3 \xrightarrow{H_2SO_4} CH_3CH_2-O-CH_2CH_3 + H_2O \qquad [24.16]$$

A reaction in which water is eliminated from two substances is called a *condensation reaction*. ∞ (Sections 12.8 and 22.8)

Both diethyl ether and the cyclic ether tetrahydrofuran, shown below, are common solvents for organic reactions. Diethyl ether was formerly used as an anesthetic (known simply as "ether" in that context), but it had significant side effects.

$$CH_3CH_2-O-CH_2CH_3$$

Diethyl ether

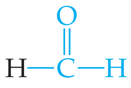


Tetrahydrofuran (THF)

Aldehydes and Ketones

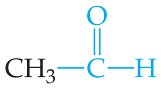
Several of the functional groups listed in Table 24.6 contain the **carbonyl group**, C═O. This group, together with the atoms attached to its carbon, defines several important functional groups that we consider in this section.

In **aldehydes**, the carbonyl group has at least one hydrogen atom attached:



$$H-\overset{\overset{\displaystyle O}{\|}}{C}-H$$

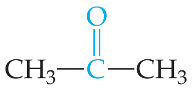
Methanal
Formaldehyde



$$CH_3-\overset{\overset{\displaystyle O}{\|}}{C}-H$$

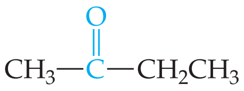
Ethanal
Acetaldehyde

In **ketones**, the carbonyl group occurs at the interior of a carbon chain and is therefore flanked by carbon atoms:



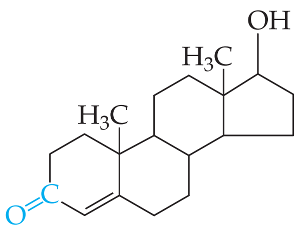
$$CH_3-\overset{\overset{\displaystyle O}{\|}}{C}-CH_3$$

Propanone
Acetone



$$CH_3-\overset{\overset{\displaystyle O}{\|}}{C}-CH_2CH_3$$

2-Butanone
Methyl ethyl ketone



Testosterone

The systematic names of aldehydes contain *-al* and that ketone names contain *-one*. Notice that testosterone has both alcohol and ketone groups; the ketone functional group dominates the molecular properties. Therefore, testosterone is considered a ketone first and an alcohol second, and its name reflects its ketone properties.

Many compounds found in nature contain an aldehyde or ketone functional group. Vanilla and cinnamon flavorings are naturally occurring aldehydes. Two isomers of the ketone carvone impart the characteristic flavors of spearmint leaves and caraway seeds.

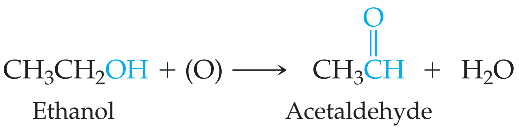
Ketones are less reactive than aldehydes and are used extensively as solvents. Acetone, the most widely used ketone, is completely miscible with water, yet it dissolves a wide range of organic substances.

Carboxylic Acids and Esters

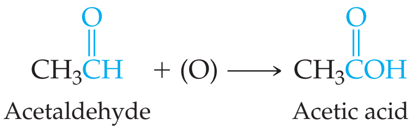
Carboxylic acids contain the *carboxyl* functional group, often written COOH. (Section 16.10) These weak acids are widely distributed in nature and are common in citrus fruits. (Section 4.3) They are also important in the manufacture of polymers used to make fibers, films, and paints. ▼ **Figure 24.13** shows the formulas of several carboxylic acids.

The common names of many carboxylic acids are based on their historical origins. Formic acid, for example, was first prepared by extraction from ants; its name is derived from the Latin word *formica*, "ant."

Carboxylic acids can be produced by oxidation of alcohols. Under appropriate conditions, the aldehyde may be isolated as the first product of oxidation, as in the sequence



$$\underset{\text{Ethanol}}{\mathrm{CH_3CH_2OH}} + (\mathrm{O}) \longrightarrow \underset{\text{Acetaldehyde}}{\mathrm{CH_3}\overset{\mathrm{O}}{\overset{\|}{\mathrm{C}}}\mathrm{H}} + \mathrm{H_2O} \tag{24.17}$$

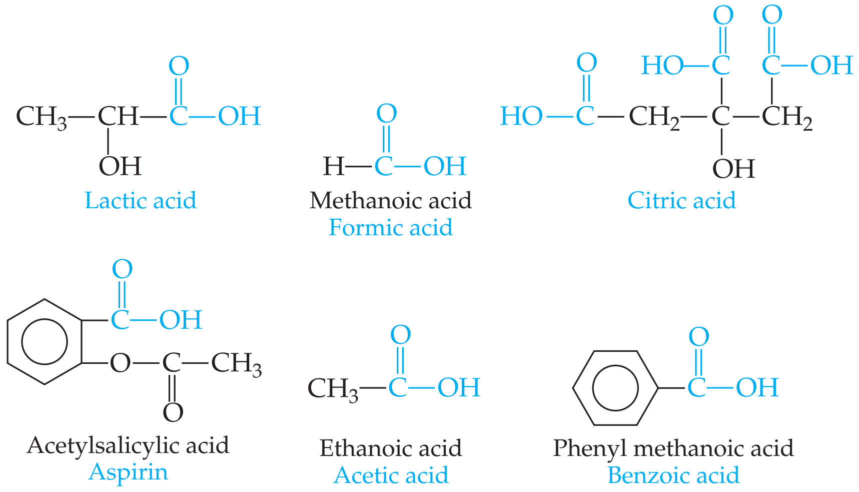


$$\underset{\text{Acetaldehyde}}{\mathrm{CH_3}\overset{\mathrm{O}}{\overset{\|}{\mathrm{C}}}\mathrm{H}} + (\mathrm{O}) \longrightarrow \underset{\text{Acetic acid}}{\mathrm{CH_3}\overset{\mathrm{O}}{\overset{\|}{\mathrm{C}}}\mathrm{OH}} \tag{24.18}$$

where (O) represents any oxidant that can provide oxygen atoms. The air oxidation of ethanol to acetic acid is responsible for causing wines to turn sour, producing vinegar.

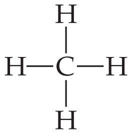
GO FIGURE

Which of these substances have both a carboxylic acid functional group and an alcohol functional group?



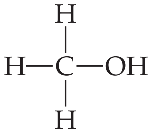
▲ **Figure 24.13 Structural formulas of common carboxylic acids.** The monocarboxylic acids are generally referred to by their common names, given in blue type.

The oxidation processes in organic compounds are related to those oxidation reactions we studied in Chapter 20. Instead of counting electrons, the number of C—O bonds is usually considered to show the extent of oxidation of similar compounds. For example, methane can be oxidized to methanol, then formaldehye (methanal), then formic acid (methanoic acid):



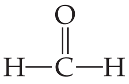
$$\begin{array}{c} \mathrm{H} \\ | \\ \mathrm{H{-}C{-}H} \\ | \\ \mathrm{H} \end{array}$$

Methane



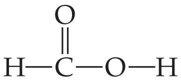
$$\begin{array}{l} \quad\;\mathrm{H} \\ \quad\;\; | \\ \mathrm{H{-}C{-}OH} \\ \quad\;\; | \\ \quad\;\mathrm{H} \end{array}$$

Methanol



$$\mathrm{H{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}H}$$

Formaldehyde



$$\mathrm{H{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}O{-}H}$$

Formic acid

From methanol to formic acid, the number of C—O bonds increases from 0 to 3 (double bonds are counted as two). If you were to calculate the oxidation state of carbon in these compounds, it would range from −4 in methane (if H's are counted as +1) to +2 in formic acid, which is consistent with carbon being oxidized. The ultimate oxidation product of any organic compound, then, is CO_2, which is indeed the product of combustion reactions of carbon-containing compounds (CO_2 has 4 C—O bonds, and C has the oxidation state +4).

Give It Some Thought

What chemical process is happening when formic acid is converted back to methane?

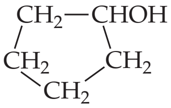
Aldehydes and ketones can be prepared by controlled oxidation of alcohols. Complete oxidation results in formation of CO_2 and H_2O, as in the burning of methanol:

$$\mathrm{CH_3OH}(g) + \tfrac{3}{2}\,\mathrm{O_2}(g) \longrightarrow \mathrm{CO_2}(g) + 2\,\mathrm{H_2O}(g)$$

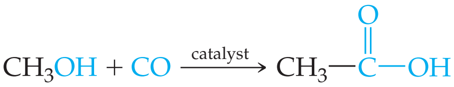
Controlled partial oxidation to form other organic substances, such as aldehydes and ketones, is carried out by using various oxidizing agents, such as air, hydrogen peroxide (H_2O_2), ozone (O_3), and potassium dichromate ($K_2Cr_2O_7$).

Give It Some Thought

Write the condensed structural formula for the acid that would result from oxidation of the alcohol



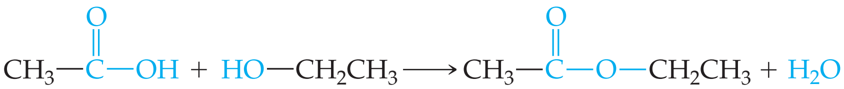
Acetic acid can also be produced by the reaction of methanol with carbon monoxide in the presence of a rhodium catalyst:



$$\mathrm{CH_3OH + CO \xrightarrow{\text{catalyst}} CH_3{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}OH} \qquad [24.19]$$

This reaction is not an oxidation; it involves, in effect, the insertion of a carbon monoxide molecule between the CH_3 and OH groups. A reaction of this kind is called *carbonylation*.

Carboxylic acids can undergo condensation reactions with alcohols to form esters:

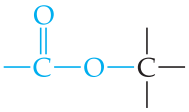


$$\mathrm{CH_3{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}OH + HO{-}CH_2CH_3 \longrightarrow CH_3{-}\overset{\overset{\displaystyle O}{\|}}{C}{-}O{-}CH_2CH_3 + H_2O}$$

Acetic acid Ethanol Ethyl acetate

[24.20]

Esters are compounds in which the H atom of a carboxylic acid is replaced by a carbon-containing group:

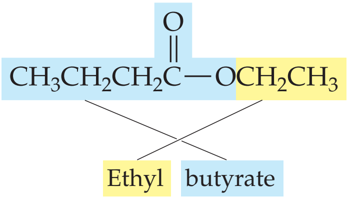


$$-\overset{\overset{\Large O}{\|}}{C}-O-\underset{|}{\overset{|}{C}}-$$

Give It Some Thought

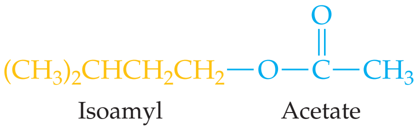
What is the difference between an ether and an ester?

The name of any ester consists of the name of the group contributed by the alcohol followed by the name of the group contributed by the carboxylic acid, with the *-ic* replaced by *-ate*. For example, the ester formed from ethyl alcohol, CH_3CH_2OH, and butyric acid, $CH_3(CH_2)_2COOH$, is



$$CH_3CH_2CH_2\overset{\overset{O}{\|}}{C}-OCH_2CH_3$$

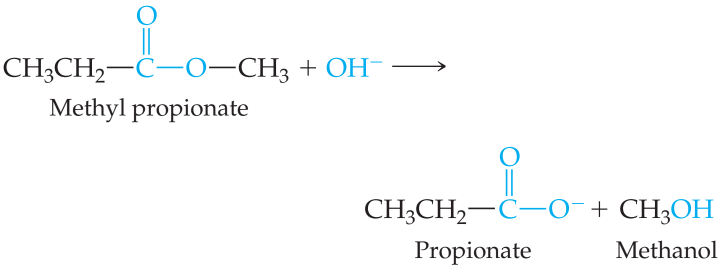
Notice that the chemical formula generally has the group originating from the acid written first, which is opposite of the way the ester is named. Another example is isoamyl acetate, the ester formed from acetic acid and isoamyl alcohol. Isoamyl acetate smells like bananas or pears.



$$(CH_3)_2CHCH_2CH_2-O-\overset{\overset{O}{\|}}{C}-CH_3$$

Many esters such as isoamyl acetate have pleasant odors and are largely responsible for the pleasing aromas of fruit.

An ester treated with an acid or a base in aqueous solution is *hydrolyzed*; that is, the molecule is split into an alcohol and a carboxylic acid or its anion:



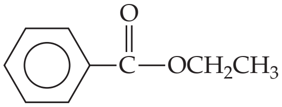
$$CH_3CH_2-\overset{\overset{O}{\|}}{C}-O-CH_3 + OH^- \longrightarrow CH_3CH_2-\overset{\overset{O}{\|}}{C}-O^- + CH_3OH \qquad [24.21]$$

The **hydrolysis** of an ester in the presence of a base is called **saponification**, a term that comes from the Latin word for soap, *sapon*. Naturally occurring esters include fats and oils, and in making soap an animal fat or a vegetable oil is boiled with a strong base. The resultant soap consists of a mixture of salts of long-chain carboxylic acids (called fatty acids), which form during the saponification reaction.

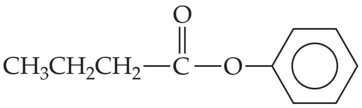
SAMPLE EXERCISE 24.6 Naming Esters and Predicting Hydrolysis Products

In a basic aqueous solution, esters react with hydroxide ion to form the salt of the carboxylic acid and the alcohol from which the ester is constituted. Name each of the following esters, and indicate the products of their reaction with aqueous base.

(a)



(b)



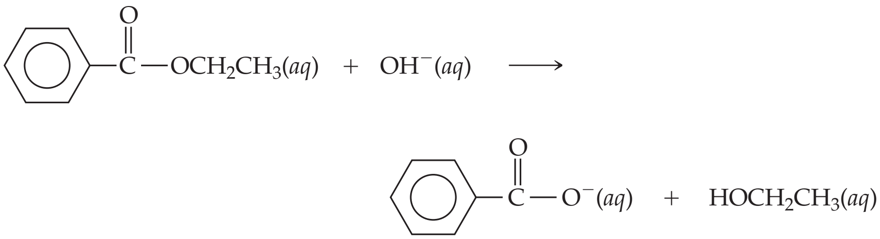
SOLUTION

Analyze We are given two esters and asked to name them and to predict the products formed when they undergo hydrolysis (split into an alcohol and carboxylate ion) in basic solution.

Plan Esters are formed by the condensation reaction between an alcohol and a carboxylic acid. To name an ester, we must analyze its structure and determine the identities of the alcohol and acid from which it is formed. We can identify the alcohol by adding an OH to the alkyl group attached to the O atom of the carboxyl (COO) group. We can identify the acid by adding an H to the O atom of the carboxyl group. We have learned that the first part of an ester name indicates the alcohol portion and the second indicates the acid portion. The name conforms to how the ester undergoes hydrolysis in base, reacting with base to form an alcohol and a carboxylate anion.

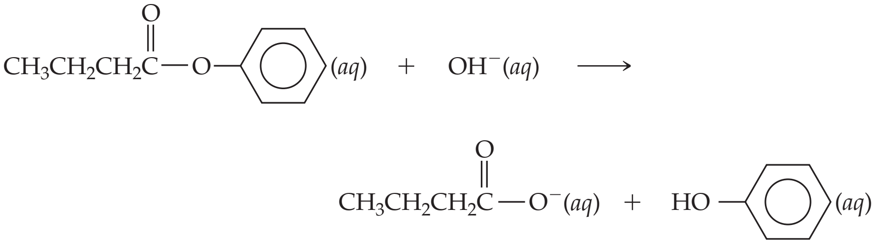
Solve

(a) This ester is derived from ethanol (CH_3CH_2OH) and benzoic acid (C_6H_5COOH). Its name is therefore ethyl benzoate. The net ionic equation for reaction of ethyl benzoate with hydroxide ion is



The products are benzoate ion and ethanol.

(b) This ester is derived from phenol (C_6H_5OH) and butanoic acid (commonly called butyric acid) ($CH_3CH_2CH_2COOH$). The residue from the phenol is called the phenyl group. The ester is therefore named phenyl butyrate or phenyl butanoate. The net ionic equation for the reaction of phenyl butyrate with hydroxide ion is



The products are butyrate ion and phenol.

Practice Exercise 1

For the generic ester RC(O)OR’, which bond will hydrolyze under basic conditions?
(a) the R—C bond **(b)** the C═O bond **(c)** the C—O bond **(d)** the O—R’ bond
(e) more than one of the above

Practice Exercise 2

Write the condensed structural formula for the ester formed from propyl alcohol and propionic acid.

Amines and Amides

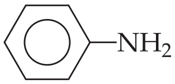
Amines are compounds in which one or more of the hydrogens of ammonia (NH_3) are replaced by an alkyl group:

$CH_3CH_2NH_2$

Ethylamine

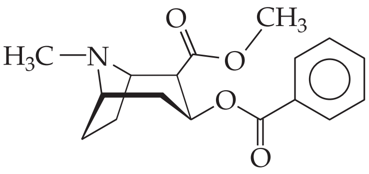
$(CH_3)_3N$

Trimethylamine

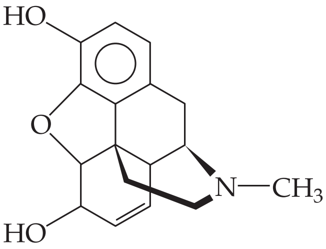


Phenylamine
Aniline

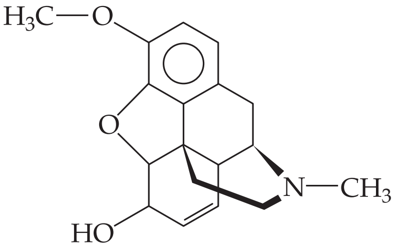
Amines are the most common organic bases. (Section 16.7) As we saw in the Chemistry Put to Work box in Section 16.8, many pharmaceutically active compounds are complex amines:



Cocaine

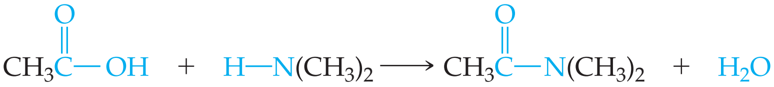


Morphine



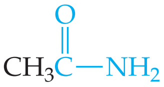
Codeine

An amine with at least one H bonded to N can undergo a condensation reaction with a carboxylic acid to form an **amide**, which contains the carbonyl group $(C{=}O)$ attached to N (Table 24.6):



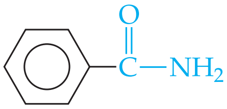
$$CH_3\overset{O}{\overset{\|}{C}}-OH + H-N(CH_3)_2 \longrightarrow CH_3\overset{O}{\overset{\|}{C}}-N(CH_3)_2 + H_2O \qquad [24.22]$$

We may consider the amide functional group to be derived from a carboxylic acid with an NRR′, NH_2 or NHR′ group replacing the OH of the acid, as in these examples:

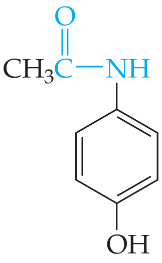


$$CH_3\overset{O}{\overset{\|}{C}}-NH_2$$

Ethanamide
Acetamide

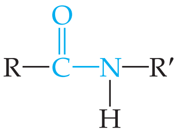


Phenylmethanamide
Benzamide



N-(4-hydroxyphenyl)ethanamide
Acetaminophen

The amide linkage

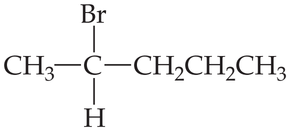


$$R-\overset{O}{\overset{\|}{C}}-\underset{\underset{H}{|}}{N}-R'$$

where R and R′ are organic groups, is the key functional group in proteins, as we will see in Section 24.7.

24.5 | Chirality in Organic Chemistry

A molecule possessing a nonsuperimposable mirror image is termed **chiral** (Greek *cheir*, "hand"). (Section 23.4) *Compounds containing carbon atoms with four different attached groups are inherently chiral.* A carbon atom with four different attached groups is called a *chiral center*. For example, consider 2-bromopentane:

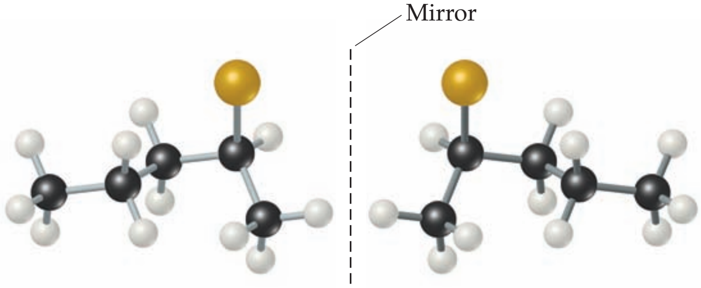


$$CH_3-\overset{\overset{\displaystyle Br}{|}}{\underset{\underset{\displaystyle H}{|}}{C}}-CH_2CH_2CH_3$$

All four groups attached to C2 are different, making that carbon a chiral center. ▼ **Figure 24.14** illustrates the nonsuperimposable mirror images of this molecule. Imagine moving the molecule shown to the left of the mirror over to the right of the mirror. If you then turn it in every possible way, you will conclude that it cannot be superimposed on the molecule shown to the right of the mirror. Nonsuperimposable mirror images are called either *optical isomers* or *enantiomers*. (Section 23.4) Organic chemists use the labels *R* and *S* to distinguish the two forms. We need not go into the rules for deciding on the labels.

GO FIGURE

If you replace Br with CH_3, will the compound be chiral?

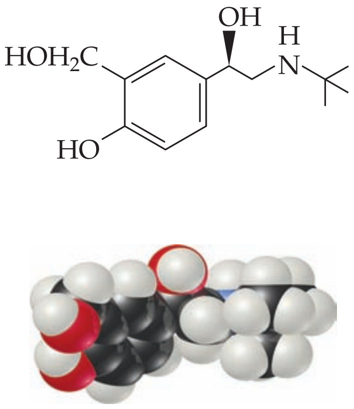


▲ **Figure 24.14 The two enantiomeric forms of 2-bromopentane.** The mirror-image isomers are not superimposable on each other.

The two members of an enantiomer pair have identical physical properties and identical chemical properties when they react with nonchiral reagents. Only in a chiral environment do they behave differently from each other. One interesting property of chiral substances is that their solutions may rotate the plane of polarized light, as explained in Section 23.4.

Chirality is common in organic compounds. It is often not observed, however, because when a chiral substance is synthesized in a typical reaction, the two enantiomers are formed in precisely the same quantity. The resulting mixture is called a *racemic mixture*, and it does not rotate the plane of polarized light because the two forms rotate the light to equal extents in opposite directions. (Section 23.4)

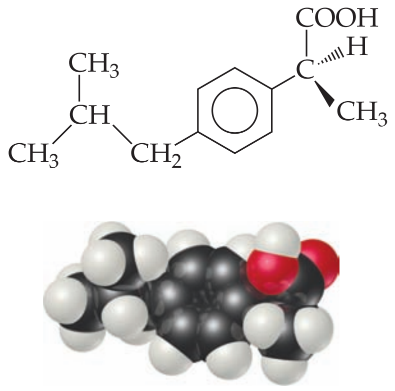
Many drugs are chiral compounds. When a drug is administered as a racemic mixture, often only one enantiomer has beneficial results. The other is often inert, or nearly so, or may even have a harmful effect. For example, the drug (*R*)-albuterol (▶ **Figure 24.15**) is a bronchodilator used to relieve the symptoms of asthma. The enantiomer (*S*)-albuterol is not only ineffective as a bronchodilator but also actually counters the effects of (*R*)-albuterol. As another example, the nonsteroidal analgesic ibuprofen is a chiral molecule usually sold as the racemic mixture. However, a preparation consisting of just the more active enantiomer, (*S*)-ibuprofen (**Figure 24.16**), relieves pain and reduces inflammation more rapidly than the racemic mixture. For this reason, the chiral version of the drug may in time come to replace the racemic one.



▲ **Figure 24.15 (*R*)-Albuterol.** This compound, which acts as a bronchodilator in patients with asthma, is one member of an enantiomer pair. The other member, (*S*)-albuterol, has the OH group pointing down, and does not have the same physiological effect.

Give It Some Thought

What are the requirements on the four groups attached to a carbon atom in order that it be a chiral center?



▲ **Figure 24.16** **(*S*)-Ibuprofen.** For relieving pain and reducing inflammation, the ability of this enantiomer far outweighs that of the (*R*) isomer. In the (*R*) isomer, the positions of the H and CH_3 group on the far-right carbon are switched.

24.6 | Introduction to Biochemistry

The functional groups discussed in Section 24.4 generate a vast array of molecules with very specific chemical reactivities. Nowhere is this specificity more apparent than in *biochemistry*—the chemistry of living organisms.

Before we discuss specific biochemical molecules, we can make some general observations. Many biologically important molecules are quite large, because organisms build biomolecules from smaller, simpler substances readily available in the biosphere. The synthesis of large molecules requires energy because most of the reactions are endothermic. The ultimate source of this energy is the Sun. Animals have essentially no capacity for using solar energy directly, and so depend on plant photosynthesis to supply the bulk of their energy needs. (Section 23.3)

In addition to requiring large amounts of energy, living organisms are highly organized. In thermodynamic terms, this high degree of organization means that the entropy of living systems is much lower than that of the raw materials from which the systems formed. Thus, living systems must continuously work against the spontaneous tendency toward increased entropy. (Section 19.3)

In the "Chemistry and Life" essays that appear throughout this text, we have introduced some important biochemical applications of fundamental chemical ideas. The remainder of this chapter will serve as only a brief introduction to other aspects of biochemistry. Nevertheless, you will see some patterns emerging. Hydrogen bonding, (Section 11.2), for example, is critical to the function of many biochemical systems, and the geometry of molecules (Section 9.1) can govern their biological importance and activity. Many of the large molecules in living systems are polymers (Section 12.8) of much smaller molecules. These **biopolymers** can be classified into three broad categories: proteins, polysaccharides (carbohydrates), and nucleic acids. Lipids are another common class of molecules in living systems, but they are usually large molecules, not biopolymers.

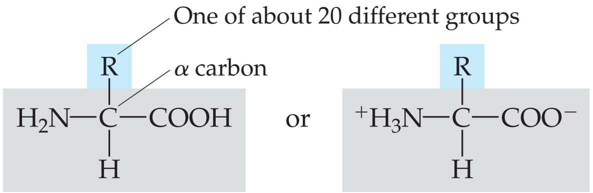
24.7 | Proteins

Proteins are macromolecules present in all living cells. About 50% of your body's dry mass is protein. Some proteins are structural components in animal tissues; they are a key part of skin, nails, cartilage, and muscles. Other proteins catalyze reactions, transport oxygen, serve as hormones to regulate specific body processes, and perform other tasks. Whatever their function, all proteins are chemically similar, being composed of smaller molecules called *amino acids*.

Amino Acids

An **amino acid** is a molecule containing an amine group, $—NH_2$, and a carboxylic acid group, —COOH. The building blocks of all proteins are *α-amino acids*, where the α (alpha) indicates that the amino group is located on the carbon atom immediately adjacent to the carboxylic acid group. Thus, there is always one carbon atom between the amino group and the carboxylic acid group.

The general formula for an α-amino acid is represented by



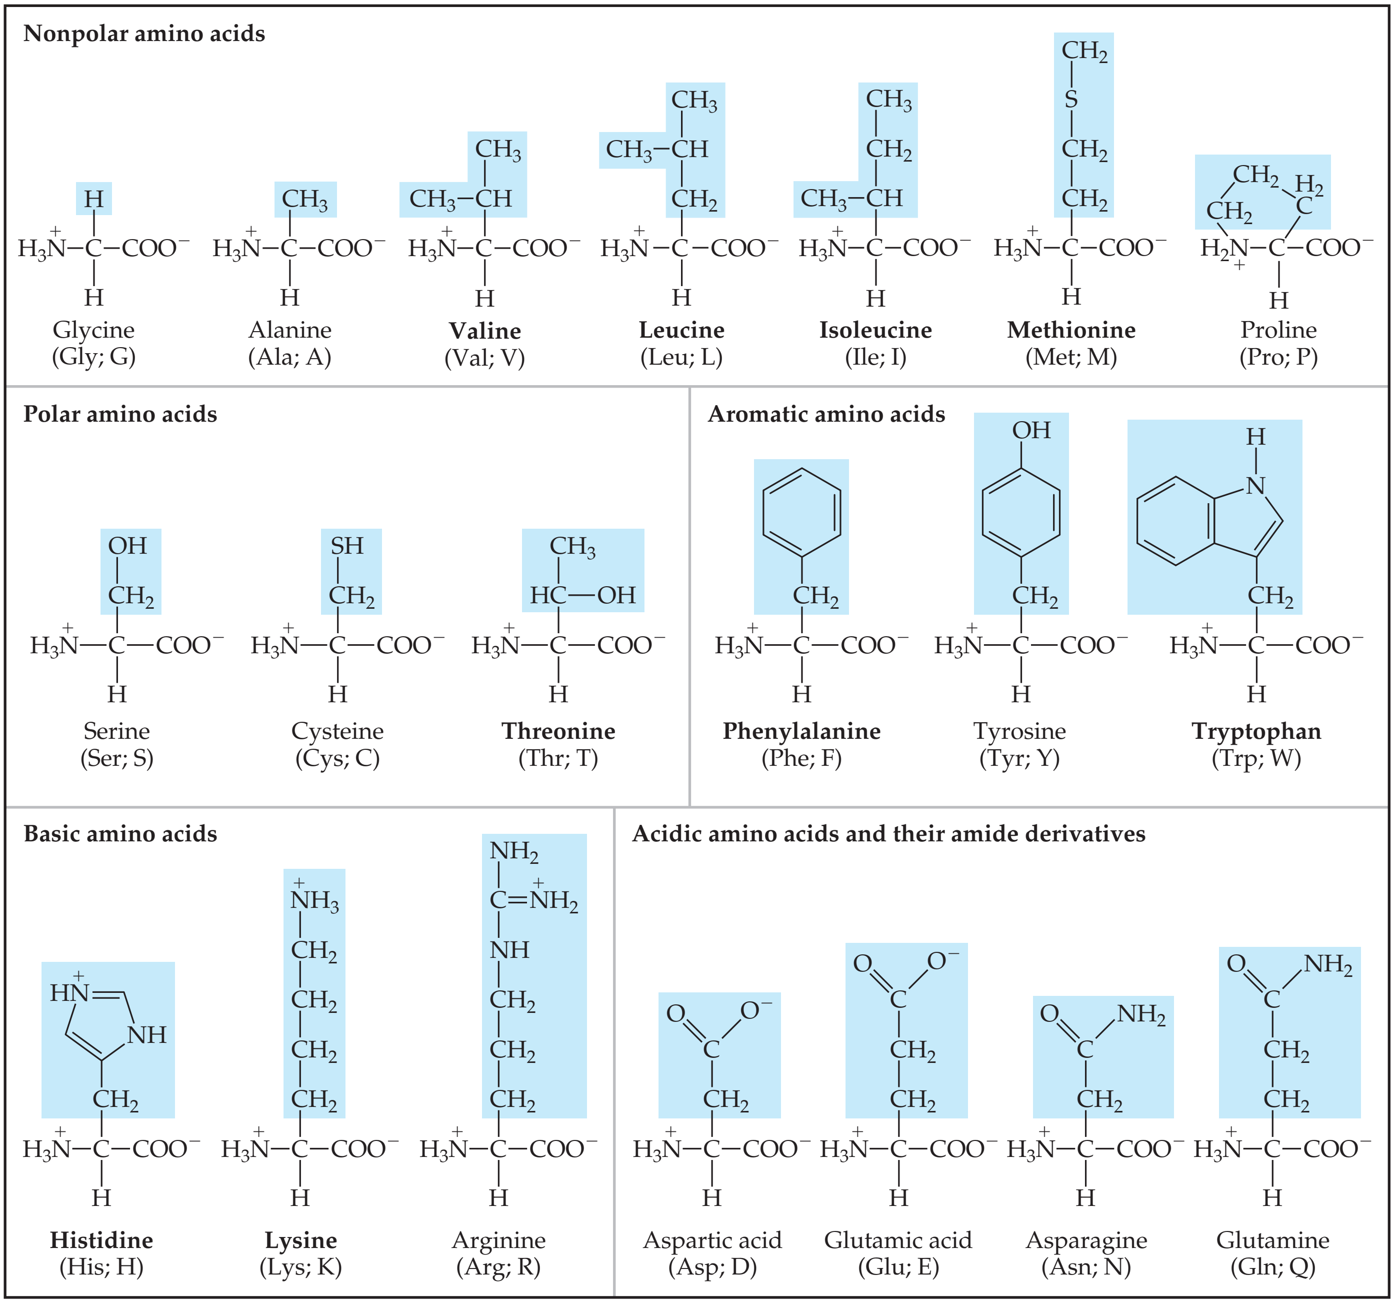
$$\begin{array}{c} R \\ | \\ H_2N—C—COOH \\ | \\ H \end{array} \quad \text{or} \quad \begin{array}{c} R \\ | \\ {}^{+}H_3N—C—COO^{-} \\ | \\ H \end{array}$$

The doubly ionized form, called a *zwitterion*, usually predominates at near-neutral pH values. This form is a result of the transfer of a proton from the carboxylic acid group to the amine group. (Section 16.10: "The Amphiprotic Behavior of Amino Acids")

Amino acids differ from one another in the nature of their R groups. Twenty-two amino acids have been identified in nature, and ▶ **Figure 24.17** shows the 20 of these 22 that are found in humans. Our bodies can synthesize 11 of these 20 amino acids in

GO FIGURE

Which group of amino acids has a net positive charge at pH 7?



Nonpolar amino acids
Glycine (Gly; G)
Alanine (Ala; A)
Valine (Val; V)
Leucine (Leu; L)

Glutamic acid (Glu; E)
Asparagine (Asn; N)
Glutamine (Gln; Q)

▲ Figure 24.17 **The 20 amino acids found in the human body.** The blue shading shows the different R groups for each amino acid. The acids are shown in the zwitterionic form in which they exist in water at near-neutral pH values. The amino acid names shown in bold are the nine essential ones.

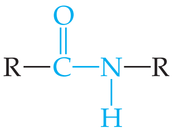
sufficient amounts for our needs. The other 9 must be ingested and are called *essential amino acids* because they are necessary components of our diet.

The α-carbon atom of the amino acids, which is the carbon between the amino and carboxylate groups, has four different groups attached to it. The amino acids are thus chiral (except for glycine, which has two hydrogens attached to the central carbon). For historical reasons, the two enantiomeric forms of amino acids are often distinguished by the labels D (from the Latin *dexter*, "right") and L (from the Latin *laevus*, "left"). Nearly all the chiral amino acids found in living organisms have the

L configuration at the chiral center. The principal exceptions are the proteins that make up the cell walls of bacteria, which can contain considerable quantities of the D isomers.

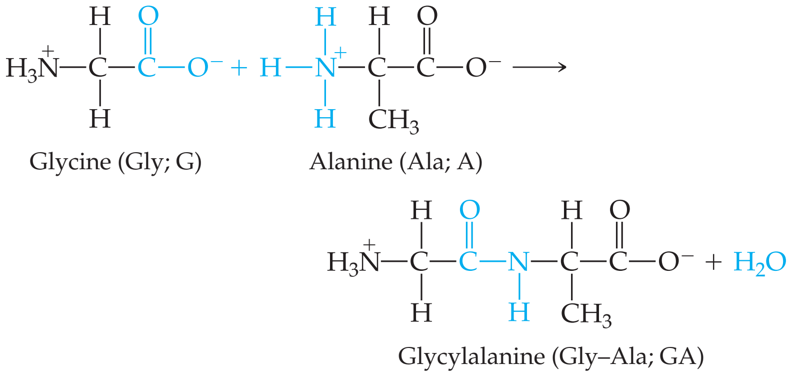
Polypeptides and Proteins

Amino acids are linked together into proteins by amide groups (Table 24.6):



$$\mathrm{R{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}\underset{\displaystyle H}{\underset{|}{N}}{-}R} \qquad [24.23]$$

Each amide group is called a **peptide bond** when it is formed by amino acids. A peptide bond is formed by a condensation reaction between the carboxyl group of one amino acid and the amino group of another amino acid. Alanine and glycine, for example, form the dipeptide glycylalanine:



Glycine (Gly; G)
Alanine (Ala; A)
Glycylalanine (Gly–Ala; GA)

The amino acid that furnishes the carboxyl group for peptide-bond formation is named first, with a *-yl* ending; then the amino acid furnishing the amino group is named. Using the abbreviations shown in Figure 24.18, glycylalanine can be abbreviated as either Gly-Ala or GA. In this notation, it is understood that the unreacted amino group is on the left and the unreacted carboxyl group on the right.

The artificial sweetener *aspartame* (◀ **Figure 24.18**) is the methyl ester of the dipeptide formed from the amino acids aspartic acid and phenylalanine.

SAMPLE EXERCISE 24.7 Drawing the Structural Formula of a Tripeptide

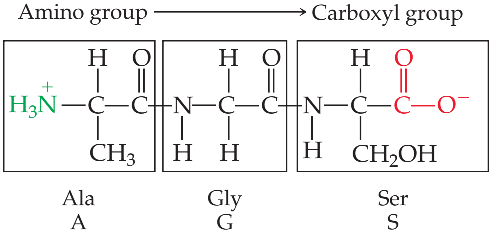
Draw the structural formula for alanylglycylserine.

SOLUTION

Analyze We are given the name of a substance with peptide bonds and asked to write its structural formula.

Plan The name of this substance suggests that three amino acids—alanine, glycine, and serine—have been linked together, forming a *tripeptide*. Note that the ending *-yl* has been added to each amino acid except for the last one, serine. By convention, the sequence of amino acids in peptides and proteins is written from the nitrogen end to the carbon end: The first-named amino acid (alanine, in this case) has a free amino group and the last-named one (serine) has a free carboxyl group.

Solve We first combine the carboxyl group of alanine with the amino group of glycine to form a peptide bond and then the carboxyl group of glycine with the amino group of serine to form another peptide bond:



Amino group
Carboxyl group
Ala
A
Gly
G
Ser
S

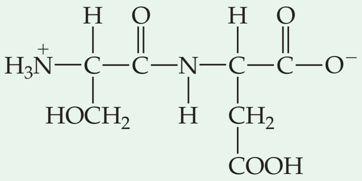
We can abbreviate this tripeptide as either Ala-Gly-Ser or AGS.

Practice Exercise 1

How many nitrogen atoms are in the tripeptide Arg-Asp-Gly?
(**a**) 3, (**b**) 4, (**c**) 5, (**d**) 6, (**e**) 7.

Practice Exercise 2

Name the dipeptide and give the two ways of writing its abbreviation.



$$H_3\overset{+}{N}-\underset{HOCH_2}{\overset{H}{C}}-\overset{O}{\overset{\|}{C}}-\underset{H}{N}-\underset{\underset{COOH}{CH_2}}{\overset{H}{C}}-\overset{O}{\overset{\|}{C}}-O^-$$

Polypeptides are formed when a large number of amino acids (>30) are linked together by peptide bonds. Proteins are linear (that is, unbranched) polypeptide molecules with molecular weights ranging from about 6000 to over 50 million amu. Because up to 22 different amino acids are linked together in proteins and because proteins consist of hundreds of amino acids, the number of possible arrangements of amino acids within proteins is virtually limitless.

Protein Structure

The sequence of amino acids along a protein chain is called its **primary structure** and gives the protein its unique identity. A change in even one amino acid can alter the biochemical characteristics of the protein. For example, sickle-cell anemia is a genetic disorder resulting from a single replacement in a protein chain in hemoglobin. The chain that is affected contains 146 amino acids. The substitution of an amino acid with a hydrocarbon side chain for one that has an acidic functional group in the side chain alters the solubility properties of the hemoglobin, and normal blood flow is impeded. (Section 13.6, "Sickle-Cell Anemia")

Proteins in living organisms are not simply long, flexible chains with random shapes. Rather, the chains self-assemble into structures based on the intermolecular forces we learned about in Chapter 11. This self-assembling leads to a protein's **secondary structure,** which refers to how segments of the protein chain are oriented in a regular pattern, as seen in **Figure 24.19**.

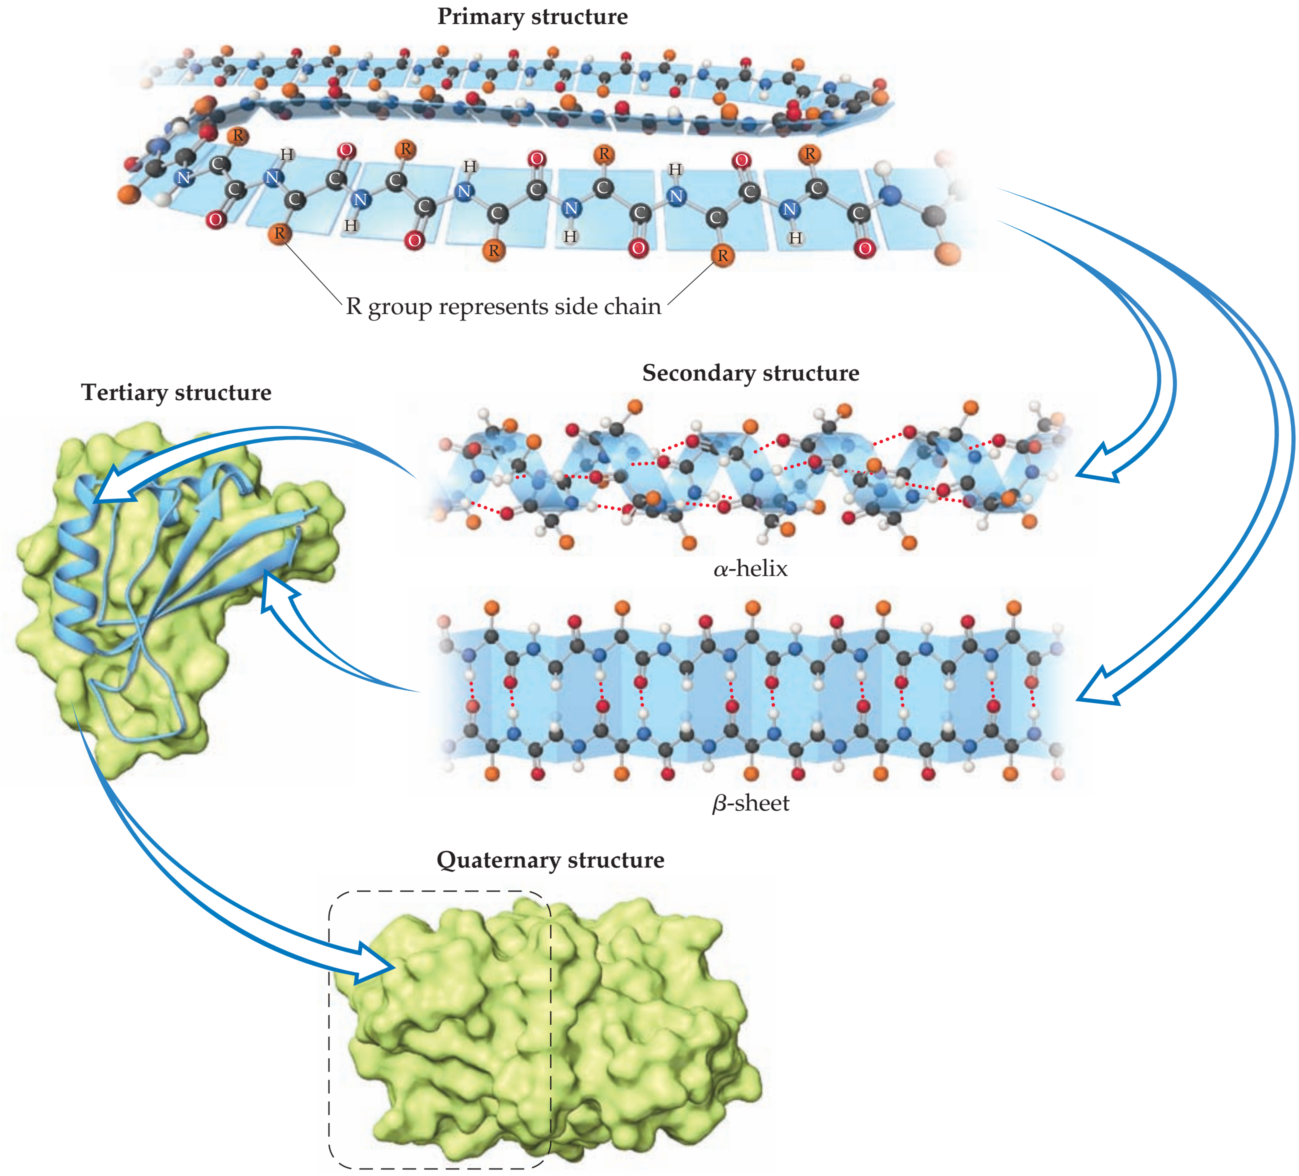
One of the most important and common secondary structure arrangements is the **α**(alpha)**-helix**. As the α-helix of Figure 24.19 shows, the helix is held in position by hydrogen bonds between amide H atoms and carbonyl O atoms. The pitch of the helix and its diameter must be such that (1) no bond angles are strained and (2) the $N-H$ and $C=O$ functional groups on adjacent turns are in proper position for hydrogen bonding. An arrangement of this kind is possible for some amino acids along the chain but not for others. Large protein molecules may contain segments of the chain that have the α-helical arrangement interspersed with sections in which the chain is in a random coil.

The other common secondary structure of proteins is the **β** (beta) **sheet**. Beta sheets are made of two or more strands of peptides that hydrogen-bond from an amide H in one strand to a carbonyl O in the other strand (Figure 24.19).

Give It Some Thought

If you heat a protein to break the intramolecular hydrogen bonds, will you maintain the α-helical or β-sheet structure?

Proteins are not active biologically unless they are in a particular shape in solution. The process by which the protein adopts its biologically active shape is called **folding**. The shape of a protein in its folded form—determined by all the bends, kinks, and sections of rodlike α-helical, β-sheet, or flexible coil components—is called the **tertiary structure**.



▲ **Figure 24.19** **The four levels of structure of proteins.**

Globular proteins fold into a compact, roughly spherical shape. Globular proteins are generally soluble in water and are mobile within cells. They have nonstructural functions, such as combating the invasion of foreign objects, transporting and storing oxygen (hemoglobin and myoglobin), and acting as catalysts. The *fibrous proteins* form a second class of proteins. In these substances the long coils align more or less in parallel to form long, water-insoluble fibers. Fibrous proteins provide structural integrity and strength to many kinds of tissue and are the main components of muscle, tendons, and hair. The largest known proteins, in excess of 27,000 amino acids long, are muscle proteins.

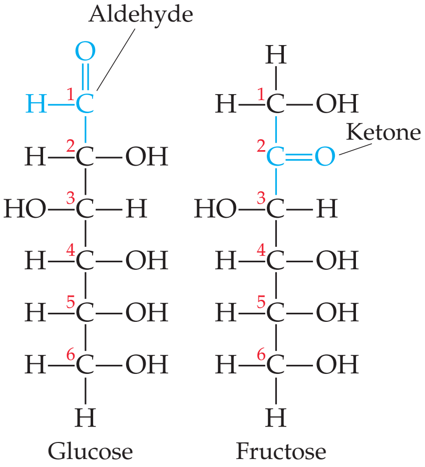
The tertiary structure of a protein is maintained by many different interactions. Certain foldings of the protein chain lead to lower energy (more stable) arrangements than do other folding patterns. For example, a globular protein dissolved in aqueous solution folds in such a way that the nonpolar hydrocarbon portions are tucked within the molecule, away from the polar water molecules. Most of the more polar acidic and basic side chains, however, project into the solution, where they can interact with water molecules through ion–dipole, dipole–dipole, or hydrogen-bonding interactions.

Some proteins are assemblies of more than one polypeptide chain. Each chain has its own tertiary structure, and two or more of these tertiary subunits may aggregate into a larger functional macromolecule. The way the tertiary subunits are arranged is called the **quaternary structure** of the protein (Figure 24.19). For example, hemoglobin, the oxygen-carrying protein of red blood cells, consists of four tertiary subunits. Each subunit contains a component called a heme with an iron atom that binds oxygen as depicted in Figure 23.15. The quaternary structure is maintained by the same types of interactions that maintain the tertiary structure.

One of the most fascinating current hypotheses in biochemistry is that misfolded proteins can cause infectious disease. These infectious misfolded proteins are called *prions*. The best example of a prion is the one thought to be responsible for mad cow disease, which can be transmitted to humans.

24.8 | Carbohydrates

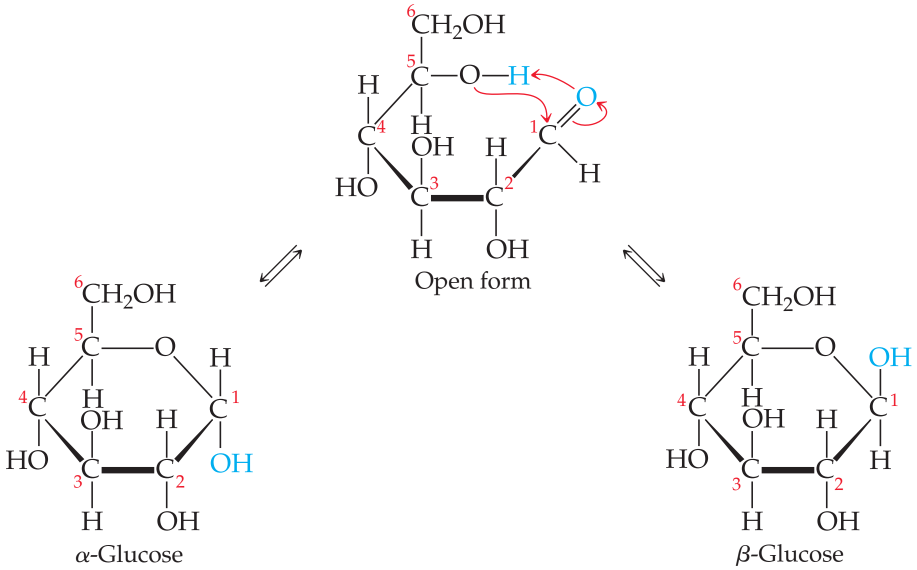
Carbohydrates are an important class of naturally occurring substances found in both plant and animal matter. The name **carbohydrate** ("hydrate of carbon") comes from the empirical formulas for most substances in this class, which can be written as $C_x(H_2O)_y$. For example, **glucose**, the most abundant carbohydrate, has the molecular formula $C_6H_{12}O_6$, or $C_6(H_2O)_6$. Carbohydrates are not really hydrates of carbon; rather, they are polyhydroxy aldehydes and ketones. Glucose, for example, is a six-carbon aldehyde sugar, whereas *fructose*, the sugar that occurs widely in fruit, is a six-carbon ketone sugar (▶ **Figure 24.20**).



▲ **Figure 24.20 Linear structure of the carbohydrates glucose and fructose.**

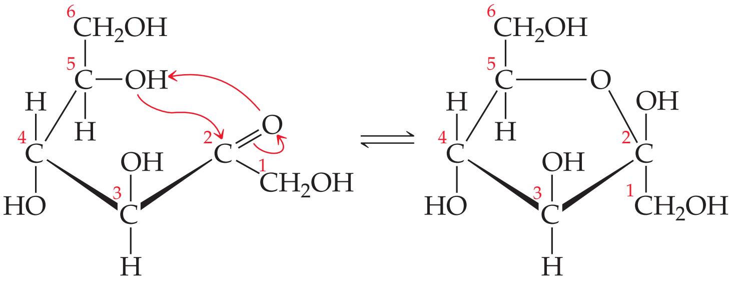
The glucose molecule, having both alcohol and aldehyde functional groups and a reasonably long and flexible backbone, can form a six-member-ring structure, as shown in ▼ **Figure 24.21**. In fact, in an aqueous solution only a small percentage of the glucose molecules are in the open-chain form. Although the ring is often drawn as if it were planar, the molecules are actually nonplanar because of the tetrahedral bond angles around the C and O atoms of the ring.

Figure 24.21 shows that the ring structure of glucose can have two relative orientations. In the α form the OH group on C1 and the CH_2OH group on C5 point in opposite directions, and in the β form they point in the same direction. Although the difference between the α and β forms might seem small, it has enormous biological consequences, including the vast difference in properties between starch and cellulose.



▲ **Figure 24.21 Cyclic glucose has an α form and a β form.**

Fructose can cyclize to form either five- or six-member rings. The five-member ring forms when the C5 OH group reacts with the C2 carbonyl group:



The six-member ring results from the reaction between the C6 OH group and the C2 carbonyl group.

SAMPLE EXERCISE 24.8 Identifying Functional Groups and Chiral Centers in Carbohydrates

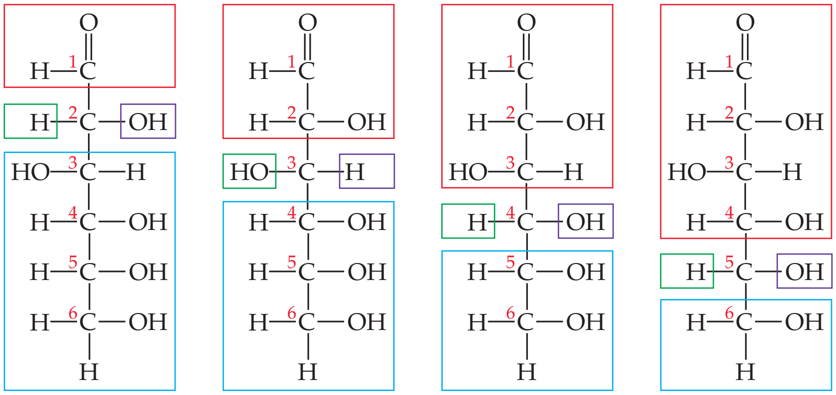
How many chiral carbon atoms are there in the open-chain form of glucose (Figure 24.20)?

SOLUTION

Analyze We are given the structure of glucose and asked to determine the number of chiral carbons in the molecule.

Plan A chiral carbon has four different groups attached (Section 24.5). We need to identify those carbon atoms in glucose.

Solve Carbons 2, 3, 4, and 5 each have four different groups attached to them:



Thus, there are four chiral carbon atoms in the glucose molecule.

Practice Exercise 1

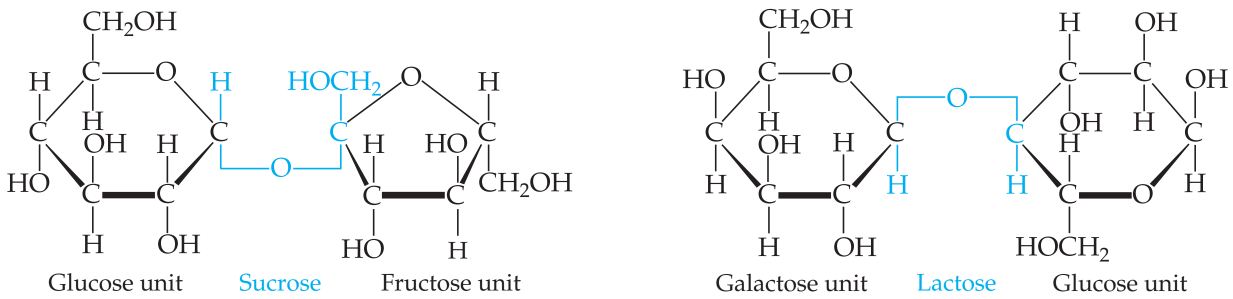
How many chiral carbon atoms are there in the open-chain form of fructose (Figure 24.20)? (**a**) 0, (**b**) 1, (**c**) 2, (**d**) 3, (**e**) 4

Practice Exercise 2

Name the functional groups present in the beta form of glucose.

Disaccharides

Both glucose and fructose are examples of **monosaccharides**, simple sugars that cannot be broken into smaller molecules by hydrolysis with aqueous acids. Two monosaccharide units can be linked together by a condensation reaction to form a **disaccharide**. The structures of two common disaccharides, *sucrose* (table sugar) and *lactose* (milk sugar), are shown in ▶ Figure 24.22.



▲ **Figure 24.22** **Two disaccharides.**

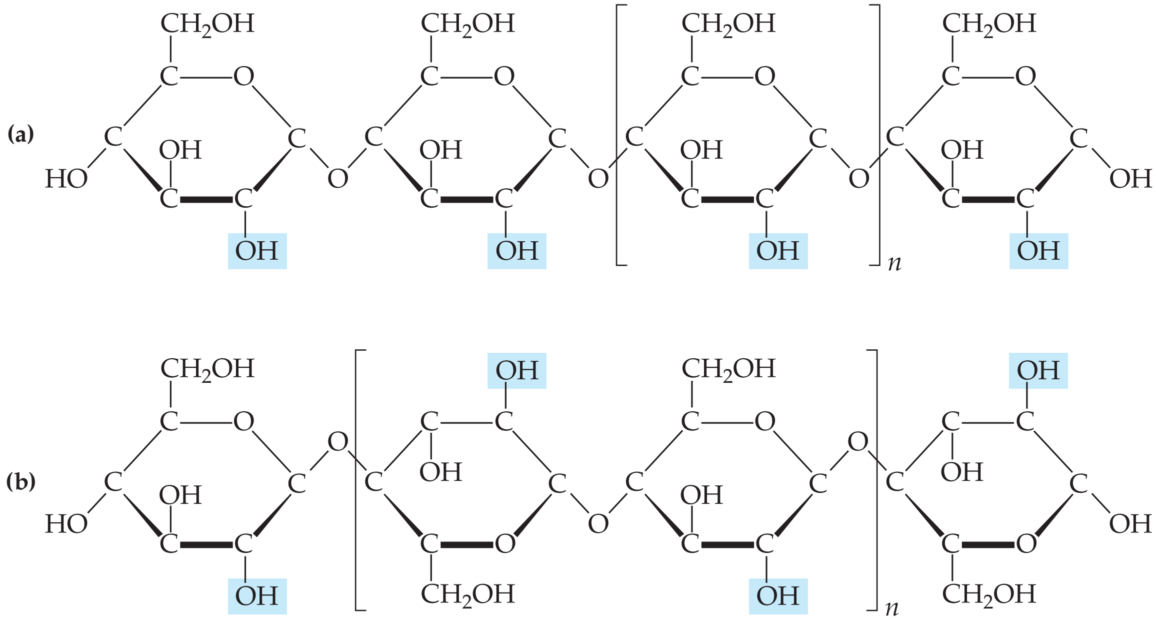
The word *sugar* makes us think of sweetness. All sugars are sweet, but they differ in the degree of sweetness we perceive when we taste them. Sucrose is about six times sweeter than lactose, slightly sweeter than glucose, but only about half as sweet as fructose. Disaccharides can be reacted with water (hydrolyzed) in the presence of an acid catalyst to form monosaccharides. When sucrose is hydrolyzed, the mixture of glucose and fructose that forms, called *invert sugar*,* is sweeter to the taste than the original sucrose. The sweet syrup present in canned fruits and candies is largely invert sugar formed from hydrolysis of added sucrose.

Polysaccharides

Polysaccharides are made up of many monosaccharide units joined together. The most important polysaccharides are starch, glycogen, and cellulose, all three of which are formed from repeating glucose units.

Starch is not a pure substance. The term refers to a group of polysaccharides found in plants. Starches serve as a major method of food storage in plant seeds and tubers. Corn, potatoes, wheat, and rice all contain substantial amounts of starch. These plant products serve as major sources of needed food energy for humans. Enzymes in the digestive system catalyze the hydrolysis of starch to glucose.

Some starch molecules are unbranched chains, whereas others are branched. ▼ Figure 24.23(a) illustrates an unbranched starch structure. Notice, in particular, that



▲ **Figure 24.23** **Structures of (a) starch and (b) cellulose.**

---

*The term *invert sugar* comes from the fact that rotation of the plane of polarized light by the glucose–fructose mixture is in the opposite direction, or inverted, from that of the sucrose solution.

the glucose units are in the α form with the bridging oxygen atoms pointing in one direction and the CH_2OH groups pointing in the opposite direction.

Glycogen is a starch-like substance synthesized in the animal body. Glycogen molecules vary in molecular weight from about 5000 to more than 5 million amu. Glycogen acts as a kind of energy bank in the body. It is concentrated in the muscles and liver. In muscles, it serves as an immediate source of energy; in the liver, it serves as a storage place for glucose and helps to maintain a constant glucose level in the blood.

Cellulose [Figure 24.23(b)] forms the major structural unit of plants. Wood is about 50% cellulose; cotton fibers are almost entirely cellulose. Cellulose consists of an unbranched chain of glucose units, with molecular weights averaging more than 500,000 amu. At first glance, this structure looks very similar to that of starch. In cellulose, however, the glucose units are in the β form with each bridging oxygen atom pointing in the same direction as the CH_2OH group in the ring to its left.

Because the individual glucose units have different relationships to one another in starch and cellulose, enzymes that readily hydrolyze starches do not hydrolyze cellulose. Thus, you might eat a pound of cellulose and receive no caloric value from it even though the heat of combustion per unit mass is essentially the same for both cellulose and starch. A pound of starch, in contrast, would represent a substantial caloric intake. The difference is that the starch is hydrolyzed to glucose, which is eventually oxidized with the release of energy. However, enzymes in the body do not readily hydrolyze cellulose, so it passes through the digestive system relatively unchanged. Many bacteria contain enzymes, called cellulases, that hydrolyze cellulose. These bacteria are present in the digestive systems of grazing animals, such as cattle, that use cellulose for food.

Give It Some Thought

Which type of linkage, α or β, would you expect to join the sugar molecules of glycogen?

24.9 | Lipids

Lipids are a diverse class of nonpolar biological molecules used by organisms for long-term energy storage (fats, oils) and as elements of biological structures (phospholipids, cell membranes, waxes).

Fats

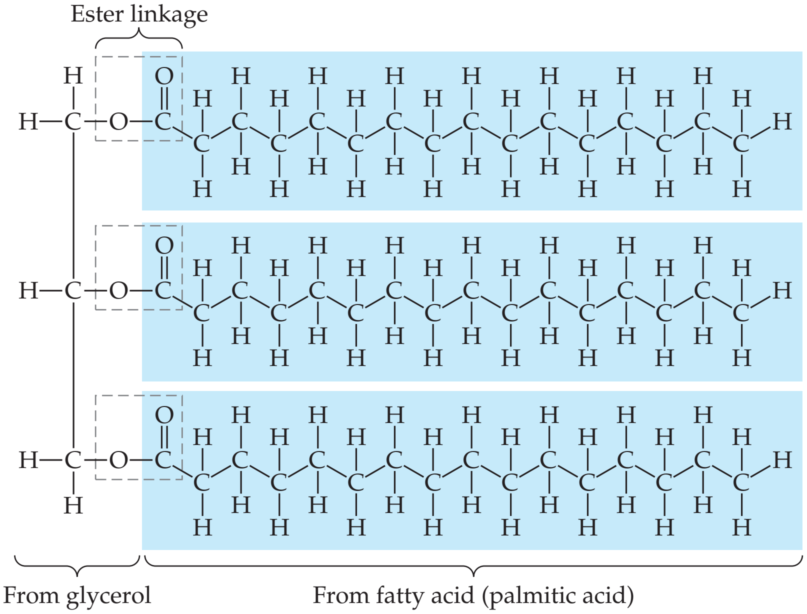
Fats are lipids derived from glyercol and fatty acids. Glycerol is an alcohol with three OH groups. Fatty acids are carboxylic acids (RCOOH) in which R is a hydrocarbon chain, usually 16 to 19 carbon atoms in length. Glycerol and fatty acids undergo condensation reactions to form ester linkages as shown in ▶ **Figure 24.24**. Three fatty acid molecules join to a glycerol. Although the three fatty acids in a fat can be the same, as they are in Figure 24.24, it is also possible that a fat contains three different fatty acids.

Lipids with saturated fatty acids are called saturated fats and are commonly solids at room temperature (such as butter and shortening). Unsaturated fats contain one or more double bonds in their carbon–carbon chains. The cis and trans nomenclature we learned for alkenes applies: Trans fats have H atoms on the opposite sides of the $C{=}C$ double bond, and cis fats have H atoms on the same sides of the $C{=}C$ double bond. Unsaturated fats (such as olive oil and peanut oil) are usually liquid at room temperature and are more often found in plants. For example, the major component (approximately 60 to 80%) of olive oil is oleic acid, *cis*-$CH_3(CH_2)_7CH{=}CH(CH_2)_7COOH$. Oleic acid is an example of a *monounsaturated* fatty acid, meaning it has only one carbon–carbon double bond in the chain. In contrast, *polyunsaturated* fatty acids have more than one carbon–carbon double bond in the chain.

For humans, trans fats are not nutritionally required, which is why some governments are moving to ban them in foods. How, then, do trans fats end up in our food? The process that converts unsaturated fats (such as oils) into saturated fats (such as

GO FIGURE

What structural features of a fat molecule cause it to be insoluble in water?



▲ **Figure 24.24** **Structure of a fat.**

shortening) is hydrogenation. (Section 24.3) The by-products of this hydrogenation process include trans fats.

Some of the fatty acids essential for human health must be available in our diets because our metabolism cannot synthesize them. These essential fatty acids are ones that have the carbon–carbon double bonds either three carbons or six carbons away from the $-CH_3$ end of the chain. These are called omega-3 and omega-6 fatty acids, where *omega* refers to the last carbon in the chain (the carboxylic acid carbon is considered the first, or alpha, one).

Phospholipids

Phospholipids are similar in chemical structure to fats but have only two fatty acids attached to a glycerol. The third alcohol group of glycerol is joined to a phosphate group (**Figure 24.25**). The phosphate group can also be attached to a small charged or polar group, such as choline, as shown in the figure. The diversity in phospholipids is based on differences in their fatty acids and in the groups attached to the phosphate group.

In water, phospholipids cluster together with their charged polar heads facing the water and their nonpolar tails facing inward. The phospholipids thus form a bilayer that is a key component of cell membranes (**Figure 24.26**).

24.10 | Nucleic Acids

Nucleic acids are a class of biopolymers that are the chemical carriers of an organism's genetic information. **Deoxyribonucleic acids (DNAs)** are huge molecules whose molecular weights may range from 6 to 16 million amu. **Ribonucleic acids (RNAs)** are smaller molecules, with molecular weights in the range of 20,000 to 40,000 amu. Whereas DNA is found primarily in the nucleus of the cell, RNA is found mostly outside the nucleus in the *cytoplasm*, the nonnuclear material enclosed by the cell membrane. DNA stores the genetic information of the cell and specifies which proteins the cell can synthesize. RNA carries the information stored by DNA out of the cell nucleus into the cytoplasm, where the information is used in protein synthesis.

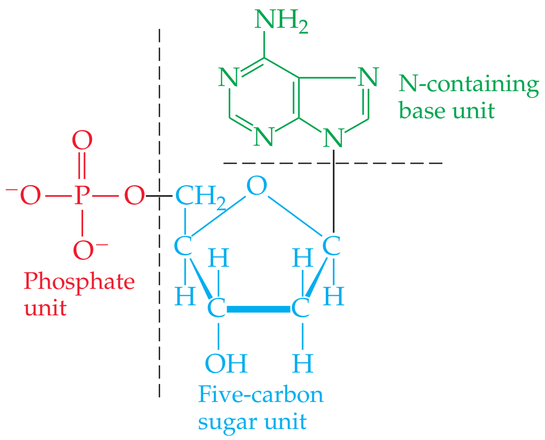
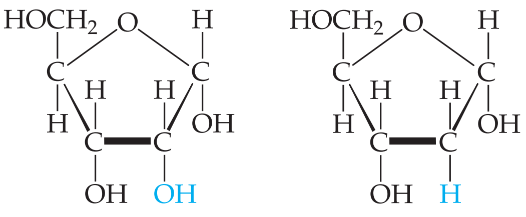
▲ **Figure 24.26** **The cell membrane.** Living cells are encased in membranes typically made of phospholipid bilayers. The bilayer structure is stabilized by the favorable interactions of the hydrophobic tails of the phospholipids, which point away from both the water inside the cell and the water outside the cell, while the charged head groups face the two water environments.

The monomers of nucleic acids, called **nucleotides**, are formed from a five-carbon sugar, a nitrogen-containing organic base, and a phosphate group. An example is shown in ▶ Figure 24.27.



▲ Figure 24.27 **A nucleotide.** Structure of deoxyadenylic acid, the nucleotide formed from phosphoric acid, the sugar deoxyribose, and the organic base adenine.

The five-carbon sugar in RNA is *ribose*, and that in DNA is *deoxyribose*:

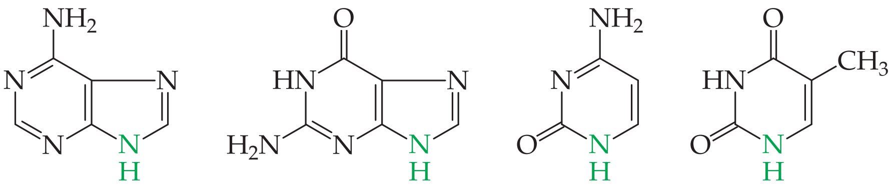


Ribose

Deoxyribose

Deoxyribose differs from ribose only in having one fewer oxygen atom at carbon 2.

There are five nitrogen-containing bases in nucleic acids:



Adenine (A)
DNA
RNA

Guanine (G)
DNA
RNA

Cytosine (C)
DNA
RNA

Thymine (T)
DNA

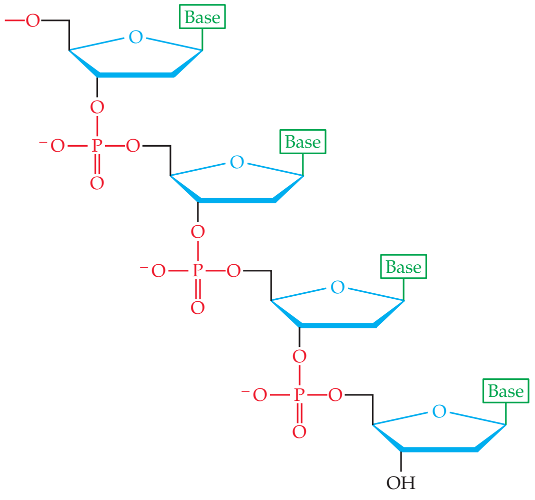
Uracil (U)
RNA

The first three bases shown here are found in both DNA and RNA. Thymine occurs only in DNA, and uracil occurs only in RNA. In either nucleic acid, each base is attached to a five-carbon sugar through a bond to the nitrogen atom shown in color.

The nucleic acids RNA and DNA are *polynucleotides* formed by condensation reactions between a phosphoric acid OH group on one nucleotide and a sugar OH group on another nucleotide. Thus, the polynucleotide strand has a backbone consisting of alternating sugar and phosphate groups with the bases extending off the chain as side groups (▶ Figure 24.28).

GO FIGURE

Is DNA positively charged, negatively charged, or neutral in aqueous solution at pH 7?



▲ Figure 24.28 **A polynucleotide.** Because the sugar in each nucleotide is deoxyribose, this polynucleotide is DNA.

The DNA strands wind together in a **double helix** (Figure 24.29). The two strands are held together by attractions between bases (represented by T, A, C, and G). These attractions involve dispersion forces, dipole–dipole forces, and hydrogen bonds. ∞∞ (Section 11.2) As shown in Figure 24.30, the structures of thymine and adenine make them perfect partners for hydrogen bonding. Likewise, cytosine and guanine form ideal hydrogen-bonding partners. We say that thymine and adenine are *complementary* to each other and cytosine and guanine are *complementary* to each other. In the double-helix structure, therefore, each thymine on one strand is opposite an adenine on the other strand, and each cytosine is opposite a guanine. The double-helix structure with complementary bases on the two strands is the key to understanding how DNA functions.

The two strands of DNA unwind during cell division, and new complementary strands are constructed on the unraveling strands (Figure 24.31). This process results in two identical double-helix DNA structures, each containing one strand from the original structure and one new strand. This replication allows genetic information to be transmitted when cells divide.

The structure of DNA is also the key to understanding protein synthesis, the means by which viruses infect cells, and many other problems of central importance to modern biology. These themes are beyond the scope of this book. If you take courses in the life sciences, however, you will learn a good deal about such matters.

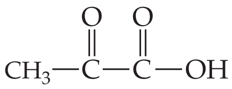
SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

Pyruvic acid,



$$CH_3-\overset{O}{\overset{\|}{C}}-\overset{O}{\overset{\|}{C}}-OH$$

is formed in the body from carbohydrate metabolism. In muscles, it is reduced to lactic acid in the course of exertion. The acid-dissociation constant for pyruvic acid is 3.2×10^{-3}. **(a)** Why does pyruvic acid have a larger acid-dissociation constant than acetic acid? **(b)** Would you expect pyruvic acid to exist primarily as the neutral acid or as dissociated ions in muscle tissue, assuming a pH of 7.4 and an initial acid concentration of 2×10^{-4} *M*? **(c)** What would you predict for the solubility properties of pyruvic acid? Explain. **(d)** What is the hybridization of each carbon atom in pyruvic acid? **(e)** Assuming H atoms as the reducing agent, write a balanced chemical equation for the reduction of pyruvic acid to lactic acid (Figure 24.13). (Although H atoms do not exist as such in biochemical systems, biochemical reducing agents deliver hydrogen for such reductions.)

SOLUTION

(a) The acid-dissociation constant for pyruvic acid should be somewhat greater than that of acetic acid because the carbonyl function on the α-carbon atom of pyruvic acid exerts an electron-withdrawing effect on the carboxylic acid group. In the $C—O—H$ bond system, the electrons are shifted from H, facilitating loss of the H as a proton. (Section 16.10)

(b) To determine the extent of ionization, we first set up the ionization equilibrium and equilibrium-constant expression. Using HPv as the symbol for the acid, we have

$$\mathrm{HPv} \rightleftharpoons \mathrm{H^+} + \mathrm{Pv^-}$$

$$K_a = \frac{[\mathrm{H^+}][\mathrm{Pv^-}]}{[\mathrm{HPv}]} = 3.2 \times 10^{-3}$$

Let $[\mathrm{Pv^-}] = x$. Then the concentration of undissociated acid is $2 \times 10^{-4} - x$. The concentration of $[\mathrm{H^+}]$ is fixed at 4.0×10^{-8} (the antilog of the pH value). Substituting, we obtain

$$3.2 \times 10^{-3} = \frac{(4.0 \times 10^{-8})(x)}{(2 \times 10^{-4} - x)}$$

Solving for x, we obtain

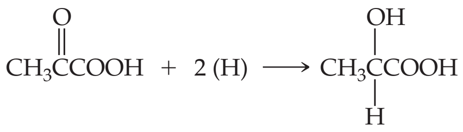
$$x = [\mathrm{Pv^-}] = 2 \times 10^{-4}\,M$$

This is the initial concentration of acid, which means that essentially all the acid has dissociated. We might have expected this result because the acid is quite dilute and the acid-dissociation constant is fairly high.

(c) Pyruvic acid should be quite soluble in water because it has polar functional groups and a small hydrocarbon component. We would predict it would be soluble in polar organic solvents, especially ones that contain oxygen. In fact, pyruvic acid dissolves in water, ethanol, and diethyl ether.

(d) The methyl group carbon has sp^3 hybridization. The carbon of the carbonyl group has sp^2 hybridization because of the double bond to oxygen. Similarly, the carboxylic acid carbon is sp^2 hybridized.

(e) The balanced chemical equation for this reaction is



$$\mathrm{CH_3}\overset{\overset{\displaystyle O}{\|}}{C}\mathrm{COOH} + 2\,(\mathrm{H}) \longrightarrow \mathrm{CH_3}\underset{\underset{\displaystyle H}{|}}{\overset{\overset{\displaystyle OH}{|}}{C}}\mathrm{COOH}$$

Essentially, the ketonic functional group has been reduced to an alcohol.

Strategies in Chemistry

What Now?

If you are reading this box, you have made it to the end of our text. We congratulate you on the tenacity and dedication that you have exhibited to make it this far!

As an epilogue, we offer the ultimate study strategy in the form of a question: What do you plan to do with the knowledge of chemistry that you have gained thus far in your studies? Many of you will enroll in additional courses in chemistry as part of your required curriculum. For others, this will be the last formal course in chemistry that you will take. Regardless of the career path you plan to take—whether it is chemistry, one of the biomedical fields, engineering, the liberal arts, or another field—we hope that this text has increased your appreciation of the chemistry in the world around you. If you pay attention, you will be aware of encounters with chemistry on a daily basis, from food and pharmaceutical labels to gasoline pumps, sports equipment to news reports.

We have also tried to give you a sense that chemistry is a dynamic, continuously changing science. Research chemists synthesize new compounds, develop new reactions, uncover chemical properties that were previously unknown, find new applications for known compounds, and refine theories. The understanding of biological systems in terms of the underlying chemistry has become increasingly important as new levels of complexity are uncovered. Solving the global challenges of sustainable energy and clean water require the work of many chemists. We encourage you to participate in the fascinating world of chemical research by taking part in an undergraduate research program. Given all the answers that chemists seem to have, you may be surprised at the large number of questions that they still find to ask.

Finally, we hope you have enjoyed using this textbook. We certainly enjoyed putting so many of our thoughts about chemistry on paper. We truly believe it to be the central science, one that benefits all who learn about it and from it.

Chapter Summary and Key Terms

GENERAL CHARACTERISTICS OF ORGANIC COMPOUNDS (INTRODUCTION AND SECTION 24.1) This chapter introduces **organic chemistry**, which is the study of carbon compounds (typically compounds containing carbon–carbon bonds), and **biochemistry**, which is the study of the chemistry of living organisms. We have encountered many aspects of organic chemistry in earlier chapters. Carbon forms four bonds in its stable compounds. The C—C single bonds and the C—H bonds tend to have low reactivity. Those bonds that have a high electron density (such as multiple bonds or bonds with an atom of high electronegativity) tend to be the sites of reactivity in an organic compound. These sites of reactivity are called **functional groups**.

INTRODUCTION OF HYDROCARBONS (SECTION 24.2) The simplest types of organic compounds are hydrocarbons, those composed of only carbon and hydrogen. There are four major kinds of hydrocarbons: alkanes, alkenes, alkynes, and aromatic hydrocarbons. **Alkanes** are composed of only C—H and C—C single bonds. **Alkenes** contain one or more carbon–carbon double bonds. **Alkynes** contain one or more carbon–carbon triple bonds. **Aromatic hydrocarbons** contain cyclic arrangements of carbon atoms bonded through both σ and delocalized π bonds. Alkanes are saturated hydrocarbons; the others are unsaturated.

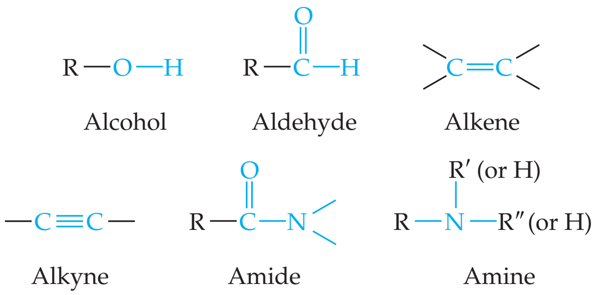
Alkanes may form straight-chain, branched-chain, and cyclic arrangements. Isomers are substances that possess the same molecular formula but differ in the arrangements of atoms. In **structural isomers**, the bonding arrangements of the atoms differ. Different isomers are given different systematic names. The naming of hydrocarbons is based on the longest continuous chain of carbon atoms in the structure. The locations of **alkyl groups**, which branch off the chain, are specified by numbering along the carbon chain.

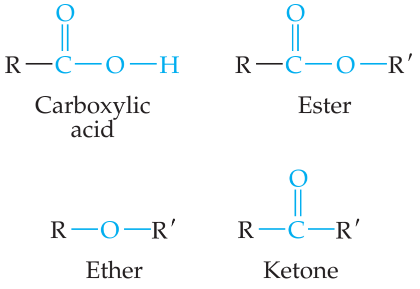
Alkanes with ring structures are called **cycloalkanes**. Alkanes are relatively unreactive. They do, however, undergo combustion in air, and their chief use is as sources of heat energy produced by combustion.

ALKENES, ALKYNES, AND AROMATIC HYDROCARBONS (SECTION 24.3) The names of alkenes and alkynes are based on the longest continuous chain of carbon atoms that contains the multiple bond, and the location of the multiple bond is specified by a numerical prefix. Alkenes exhibit not only structural isomerism but geometric (*cis–trans*) isomerism as well. In **geometric isomers**, the bonds are the same, but the molecules have different geometries. Geometric isomerism is possible in alkenes because rotation about the C═C double bond is restricted.

Alkenes and alkynes readily undergo **addition reactions** to the carbon–carbon multiple bonds. Additions of acids, such as HBr, proceed via a rate-determining step in which a proton is transferred to one of the alkene or alkyne carbon atoms. Addition reactions are difficult to carry out with aromatic hydrocarbons, but **substitution reactions** are easily accomplished in the presence of catalysts.

ORGANIC FUNCTIONAL GROUPS (SECTION 24.4) The chemistry of organic compounds is dominated by the nature of their functional groups. The functional groups we have considered are





R, R′, and R″ represent hydrocarbon groups—for example, methyl (CH_3) or phenyl (C_6H_5).

Alcohols are hydrocarbon derivatives containing one or more OH groups. **Ethers** are formed by a condensation reaction of two molecules of alcohol. Several functional groups contain the **carbonyl** (C═O) **group**, including **aldehydes**, **ketones**, **carboxylic acids**, **esters**, and **amides**. Aldehydes and ketones can be produced by the oxidation of certain alcohols. Further oxidation of the aldehydes produces carboxylic acids. Carboxylic acids can form esters by a condensation reaction with alcohols, or they can form amides by a condensation reaction with amines. Esters undergo **hydrolysis** (**saponification**) in the presence of strong bases.

CHIRALITY IN ORGANIC CHEMISTRY (SECTION 24.5) Molecules that possess nonsuperimposable mirror images are termed **chiral**. The two nonsuperimposable forms of a chiral molecule are called *enantiomers*. In carbon compounds, a chiral center is created when all four groups bonded to a central carbon atom are different, as in 2-bromobutane. Many of the molecules occurring in living systems, such as the amino acids, are chiral and exist in nature in only one enantiomeric form. Many drugs of importance in human medicine are chiral, and the enantiomers may produce very different biochemical effects. For this reason, synthesis of only the effective enantiomers of chiral drugs has become a high priority.

INTRODUCTION TO BIOCHEMISTRY; PROTEINS (SECTIONS 24.6 AND 24.7) Many of the molecules that are essential for life are large natural polymers that are constructed from smaller molecules called monomers. Three of these **biopolymers** are considered in this chapter: proteins, polysaccharides (carbohydrates), and nucleic acids.

Proteins are polymers of **amino acids**. They are the major structural materials in animal systems. All naturally occurring proteins are formed from 22 amino acids, although only 20 are common. The amino acids are linked by **peptide bonds**. A **polypeptide** is a polymer formed by linking many amino acids by peptide bonds.

Amino acids are chiral substances. Usually only one of the enantiomers is found to be biologically active. Protein structure is determined by the sequence of amino acids in the chain (its **primary structure**), the intramolecular interactions within the chain (its **secondary structure**), and the overall shape of the complete molecule (its **tertiary structure**). Two important secondary structures are the **α-helix** and the **β-sheet**. The process by which a protein assumes its biologically active tertiary structure is called **folding**. Sometimes several proteins aggregate together to form a **quaternary structure**.

CARBOHYDRATES AND LIPIDS (SECTIONS 24.8 AND 24.9) **Carbohydrates**, which are polyhydroxy aldehydes and ketones, are the major structural constituents of plants and are a source of energy in both plants and animals. **Glucose** is the most common **monosaccharide**, or simple sugar. Two monosaccharides can be linked together by means of a condensation reaction to form a **disaccharide. Polysaccharides** are complex carbohydrates made up of many monosaccharide units joined together. The three most important polysaccharides are **starch**, which is found in plants; **glycogen**, which is found in mammals; and **cellulose**, which is also found in plants.

Lipids are compounds derived from glycerol and fatty acids and include fats and **phospholipids**. Fatty acids can be saturated, unsaturated, cis, or trans depending on their chemical formulas and structures.

NUCLEIC ACIDS (SECTION 24.10) **Nucleic acids** are biopolymers that carry the genetic information necessary for cell reproduction; they also control cell development through control of protein synthesis. The building blocks of these biopolymers are **nucleotides**. There are two types of nucleic acids, **ribonucleic acids (RNA)** and **deoxyribonucleic acids (DNA)**. These substances consist of a polymeric backbone of alternating phosphate and ribose or deoxyribose sugar groups with organic bases attached to the sugar molecules. The DNA polymer is a double-stranded helix (**double helix**) held together by hydrogen bonding between matching organic bases situated across from one another on the two strands. The hydrogen bonding between specific base pairs is the key to gene replication and protein synthesis.

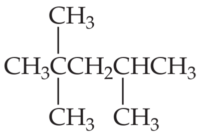
Learning Outcomes After studying this chapter, you should be able to:

- Distinguish among alkanes, alkenes, alkynes, and aromatic hydrocarbons. (Section 24.2)
- Draw hydrocarbon structures based on their names and name hydrocarbons based on their structures. (Sections 24.2 and 24.3)
- Predict the products of addition reactions and substitution reactions. (Section 24.3)
- Draw the structures of the functional groups: alkene, alkyne, alcohol, haloalkane, carbonyl, ether, aldehyde, ketone, carboxylic acid, ester, amine, and amide. (Section 24.4)
- Predict the oxidation products of organic compounds. (Section 24.4)
- Understand what makes a compound chiral and be able to recognize a chiral substance. (Section 24.5)
- Recognize the amino acids and understand how they form peptides and proteins via amide bond formation. (Section 24.7)
- Understand the differences among the primary, secondary, tertiary, and quaternary structures of proteins. (Section 24.7)
- Explain the difference between α-helix and β-sheet peptide and protein structures. (Section 24.7)
- Distinguish between starch and cellulose structures. (Section 24.8)
- Classify molecules as saccharides or lipids based on their structures. (Sections 24.8 and 24.9)
- Explain the difference between a saturated and unsaturated fat. (Section 24.9)
- Explain the structure of nucleic acids and the role played by complementary bases in DNA replication. (Section 24.10)

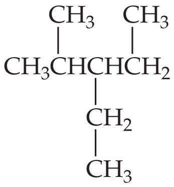
Exercises

Visualizing Concepts

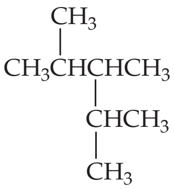
24.1 All the structures shown here have the molecular formula C_8H_{18}. Which structures are the same molecule? (*Hint:* One way to answer this question is to determine the chemical name for each structure.) [Section 24.2]

(a)


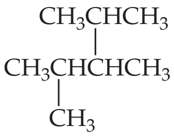
$CH_3\underset{CH_3}{\overset{CH_3}{C}}CH_2\underset{CH_3}{C}HCH_3$

(b)


$CH_3\overset{CH_3}{C}H\underset{\underset{CH_3}{CH_2}}{C}H\overset{CH_3}{C}H_2$

(c)


$CH_3\overset{CH_3}{C}H\underset{\underset{CH_3}{CHCH_3}}{C}HCH_3$

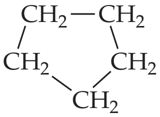
(d)


$CH_3\underset{CH_3}{C}H\overset{CH_3CHCH_3}{C}HCH_3$

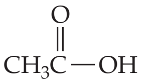
24.2 Which of these molecules is unsaturated? [Section 24.3]

$CH_3CH_2CH_2CH_3$

(a)



(b)



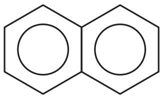
$CH_3\overset{O}{\overset{\|}{C}}-OH$

(c)

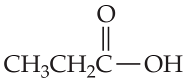
$CH_3CH{=}CHCH_3$

(d)

24.3 (**a**) Which of these molecules most readily undergoes an addition reaction? (**b**) Which of these molecules is aromatic? (**c**) Which of these molecules most readily undergoes a substitution reaction? [Section 24.3]

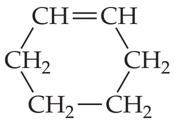


(i)

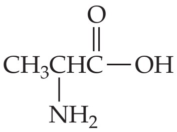


$CH_3CH_2\overset{O}{\overset{\|}{C}}-OH$

(ii)



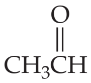
(iii)



$CH_3\underset{NH_2}{C}H\overset{O}{\overset{\|}{C}}-OH$

(iv)

24.4 (**a**) Which of these compounds would you expect to have the highest boiling point? Which of the factors that determines boiling points described in Section 11.2 primarily accounts for this highest boiling point? (**b**) Which of these compounds is the most oxidized? (**c**) Which of these compounds, if any, is an ether? (**d**) Which of these compounds, if any, is an ester? (**e**) Which of these compounds, if any, is a ketone? [Section 24.4]



$CH_3\overset{O}{\overset{\|}{C}}H$

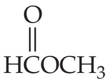
(i)

CH_3CH_2OH

(ii)

$CH_3C{\equiv}CH$

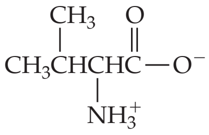
(iii)



$H\overset{O}{\overset{\|}{C}}OCH_3$

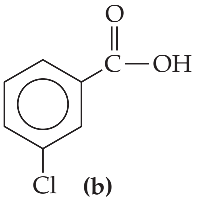
(iv)

24.5 Which of these compounds has an isomer? In each case where isomerism is possible, identify the type or types of isomerism. [Sections 24.2, 24.4]



$CH_3\overset{CH_3}{\overset{|}{C}}H\underset{NH_3^+}{\underset{|}{C}}H\overset{O}{\overset{\|}{C}}{-}O^-$

(a)



(b)

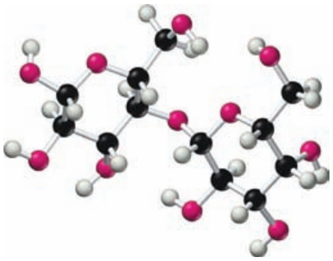
$CH_3CH_2CH{=}CHCH_3$

(c)

$CH_3CH_2CH_3$

(d)

24.6 From examination of the molecular models i–v, choose the substance that (**a**) can be hydrolyzed to form a solution containing glucose, (**b**) is capable of forming a zwitterion, (**c**) is one of the four bases present in DNA, (**d**) reacts with an acid to form an ester, (**e**) is a lipid. [Sections 24.6–24.10]



(i)

Introduction to Organic Compounds; Hydrocarbons (Sections 24.1 and 24.2)

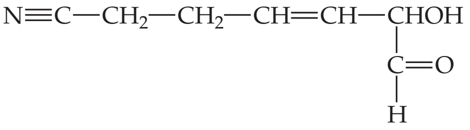
24.7 Indicate whether each statement is true or false. (**a**) Butane contains carbons that are sp^2 hybridized. (**b**) Cyclohexane is another name for benzene. (**c**) The isopropyl group contains three sp^3-hybridized carbons. (**d**) Olefin is another name for alkyne.

24.8 Indicate whether each statement is true or false. (**a**) Pentane has a higher molar mass than hexane. (**b**) The longer the linear alkyl chain for straight-chain hydrocarbons, the higher the boiling point. (**c**) The local geometry around the alkyne group is linear. (**d**) Propane has two structural isomers.

24.9 Predict the ideal values for the bond angles about each carbon atom in the following molecule. Indicate the hybridization of orbitals for each carbon.

$$CH_3CCCH_2COOH$$

24.10 Identify the carbon atom(s) in the structure shown that has (have) each of the following hybridizations: (**a**) sp^3, (**b**) sp, (**c**) sp^2.



$$N{\equiv}C{-}CH_2{-}CH_2{-}CH{=}CH{-}\underset{\begin{array}{c}|\\C{=}O\\|\\H\end{array}}{C}HOH$$

24.11 Is ammonia an organic molecule? Explain.

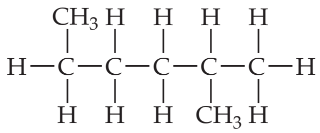
24.12 Considering the comparative values of C—H, C—C, C—O, and C—Cl bond enthalpies (Table 8.4), predict whether compounds containing C—O and C—Cl bonds are more or less reactive than simple alkane hydrocarbons.

24.13 Indicate whether each statement is true or false. (**a**) Alkanes do not contain any carbon–carbon multiple bonds. (**b**) Cyclobutane contains a four-membered ring. (**c**) Alkenes contain carbon–carbon triple bonds. (**d**) Alkynes contain carbon–carbon double bonds. (**e**) Pentane is a saturated hydrocarbon but 1-pentene is an unsaturated hydrocarbon. (**f**) Cyclohexane is an aromatic hydrocarbon. (**g**) The methyl group contains one less hydrogen atom than methane.

24.14 What structural features help us identify a compound as (**a**) an alkane, (**b**) a cycloalkane, (**c**) an alkene, (**d**) an alkyne, (**e**) a saturated hydrocarbon, (**f**) an aromatic hydrocarbon?

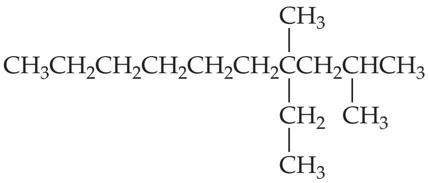
24.15 Give the the name or condensed structural formula, as appropriate:

(a)



$$H{-}\underset{H}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}}{-}\underset{H}{\underset{|}{\overset{H}{\overset{|}{C}}}}{-}\underset{H}{\underset{|}{\overset{H}{\overset{|}{C}}}}{-}\underset{CH_3}{\underset{|}{\overset{H}{\overset{|}{C}}}}{-}\underset{H}{\underset{|}{\overset{H}{\overset{|}{C}}}}{-}H$$

(b)



$$CH_3CH_2CH_2CH_2CH_2CH_2\overset{CH_3}{\overset{|}{\underset{\begin{array}{c}|\\CH_2\\|\\CH_3\end{array}}{C}}}CH_2\underset{\begin{array}{c}|\\CH_3\end{array}}{C}HCH_3$$

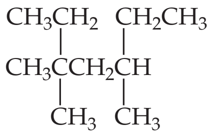
(**c**) 2-methylheptane

(**d**) 4-ethyl-2,3-dimethyloctane

(**e**) 1,2-dimethylcyclohexane

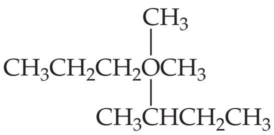
24.16 Give the name or condensed structural formula, as appropriate:

(a)



$CH_3\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3CH_2}{|}}{C}}CH_2\underset{\underset{CH_3}{|}}{\overset{\overset{CH_2CH_3}{|}}{C}}H$

(b)

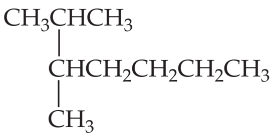


$CH_3CH_2CH_2\underset{\underset{CH_3CHCH_2CH_3}{|}}{\overset{\overset{CH_3}{|}}{O}}CH_3$

(c) 2,5,6-trimethylnonane
(d) 3-propyl-4,5-dimethylundecane
(e) 1-ethyl-3-methylcyclohexane

24.17 Give the name or condensed structural formula, as appropriate:

(a)

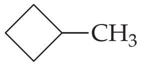


$CH_3\overset{}{C}HCH_3$
$\underset{\underset{CH_3}{|}}{\overset{|}{C}}HCH_2CH_2CH_2CH_3$

(b) 2,2-dimethylpentane
(c) 4-ethyl-1,1-dimethylcyclohexane
(d) $(CH_3)_2CHCH_2CH_2C(CH_3)_3$
(e) $CH_3CH_2CH(C_2H_5)CH_2CH_2CH_2CH_3$

24.18 Give the name or condensed structural formula, as appropriate:

(a) 3-phenylpentane
(b) 2,3-dimethylhexane
(c) 2-ethyl-2-methylheptane
(d) $CH_3CH_2CH(CH_3)CH_2CH(CH_3)_2$
(e)



24.19 What is the octane number of a mixture that is 35% heptane and 65% isooctane?

24.20 Describe two ways in which the octane number of a gasoline consisting of alkanes can be increased.

Alkenes, Alkynes, and Aromatic Hydrocarbons (Section 24.3)

24.21 **(a)** Why are alkanes said to be saturated? **(b)** Is C_4H_6 a saturated hydrocarbon? Explain.

24.22 **(a)** Is the compound $CH_3CH{=}CH_2$ saturated or unsaturated? Explain. **(b)** What is wrong with the formula $CH_3CH_2CH{=}CH_3$?

24.23 Give the molecular formula of a hydrocarbon containing five carbon atoms that is **(a)** an alkane, **(b)** a cycloalkane, **(c)** an alkene, **(d)** an alkyne.

24.24 Give the molecular formula of a hydrocarbon containing six carbon atoms that is (**a**) a cyclic alkane, (**b**) a cyclic alkene, (**c**) a linear alkyne, (**d**) an aromatic hydrocarbon.

24.25 Enediynes are a class of compounds that include some antibiotic drugs. Draw the structure of an "enediyne" fragment that contains six carbons in a row.

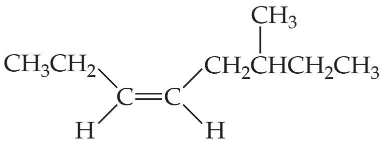
24.26 Give the general formula for any cyclic alkene, that is, a cyclic hydrocarbon with one double bond.

24.27 Write the condensed structural formulas for two alkenes and one alkyne that all have the molecular formula C_6H_{10}.

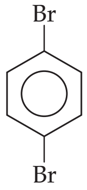
24.28 Draw all the possible noncyclic structural isomers of C_5H_{10}. Name each compound.

24.29 Name or write the condensed structural formula for the following compounds:

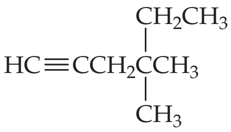
(a) *trans*-2-pentene
(b) 2,5-dimethyl-4-octene
(c)



(d)



(e)



$HC{\equiv}CCH_2\underset{\underset{CH_3}{|}}{\overset{\overset{CH_2CH_3}{|}}{C}}CH_3$

24.30 Name or write the condensed structural formula for the following compounds:

(a) 4-methyl-2-pentene
(b) *cis*-2,5-dimethyl-3-hexene
(c) *ortho*-dimethylbenzene
(d) $HC{\equiv}CCH_2CH_3$
(e) *trans*-$CH_3CH{=}CHCH_2CH_2CH_2CH_3$

24.31 Indicate whether each statement is true or false. (**a**) Two geometric isomers of pentane are *n*-pentane and neopentane. (**b**) Alkenes can have cis and trans isomers around the CC double bond. (**c**) Alkynes can have cis and trans isomers around the CC triple bond.

24.32 Draw all structural and geometric isomers of butene and name them.

24.33 Indicate whether each of the following molecules is capable of geometrical isomerism. For those that are, draw the structures: **(a)** 1,1-dichloro-1-butene, **(b)** 2,4-dichloro-2-butene, **(c)** 1,4-dichlorobenzene, **(d)** 4,4-dimethyl-2-pentyne.

24.34 Draw the three distinct geometric isomers of 2,4-hexadiene.

24.35 **(a)** True or false: Alkenes undergo addition reactions and aromatic hydrocarbons undergo substitution reactions. **(b)** Using condensed structural formulas, write the balanced equation for the reaction of 2-pentene with Br_2 and name the resulting compound. Is this an addition or a substitution reaction? **(c)** Write a balanced chemical equation for the reaction of Cl_2 with benzene to make *para*-dichlorobenzene in the presence of $FeCl_3$ as a catalyst. Is this an addition or a substitution reaction?

24.36 Using condensed structural formulas, write a balanced chemical equation for each of the following reactions: **(a)** hydrogenation of cyclohexene, **(b)** addition of H_2O to *trans*-2-pentene using H_2SO_4 as a catalyst (two products), **(c)** reaction of 2-chloropropane with benzene in the presence of $AlCl_3$.

24.37 **(a)** When cyclopropane is treated with HI, 1-iodopropane is formed. A similar type of reaction does not occur with cyclopentane or cyclohexane. Suggest an explanation for cyclopropane's reactivity. **(b)** Suggest a method of preparing ethylbenzene, starting with benzene and ethylene as the only organic reagents.

24.38 **(a)** One test for the presence of an alkene is to add a small amount of bromine, which is a red-brown liquid, and look for the disappearance of the red-brown color. This test does not work for detecting the presence of an aromatic hydrocarbon. Explain. **(b)** Write a series of reactions leading to *para*-bromoethylbenzene, beginning with benzene and using other reagents as needed. What isomeric side products might also be formed?

24.39 The rate law for addition of Br_2 to an alkene is first order in Br_2 and first order in the alkene. Does this information suggest that the mechanism of addition of Br_2 to an alkene proceeds in the same manner as for addition of HBr? Explain.

24.40 Describe the intermediate that is thought to form in the addition of a hydrogen halide to an alkene, using cyclohexene as the alkene in your description.

24.41 The molar heat of combustion of gaseous cyclopropane is −2089 kJ/mol; that for gaseous cyclopentane is −3317 kJ/mol. Calculate the heat of combustion per CH_2 group in the two cases, and account for the difference.

24.42 The heat of combustion of decahydronaphthalene ($C_{10}H_{18}$) is −6286 kJ/mol. The heat of combustion of naphthalene ($C_{10}H_8$) is −5157 kJ/mol. (In both cases $CO_2(g)$ and $H_2O(l)$ are the products.) Using these data and data in Appendix C, calculate the heat of hydrogenation and the resonance energy of naphthalene.

Functional Groups and Chirality (Sections 24.4 and 24.5)

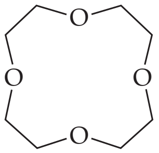
24.43 **(a)** Which of the following compounds, if any, is an ether? **(b)** Which compound, if any, is an alcohol? **(c)** Which compound, if any, would produce a basic solution if dissolved in water? (Assume solubility is not a problem). **(d)** Which compound, if any, is a ketone? **(e)** Which compound, if any, is an aldehyde?

(i) $H_3C{-}CH_2{-}OH$

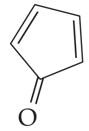
(ii)

$H_3C{-}\overset{H}{N}{-}CH_2CH{=}CH_2$

(ii)



(iv)

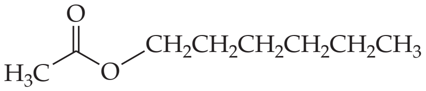


(v) $CH_3CH_2CH_2CH_2CHO$

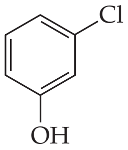
(vi) $CH_3C{\equiv}CCH_2COOH$

24.44 Identify the functional groups in each of the following compounds:

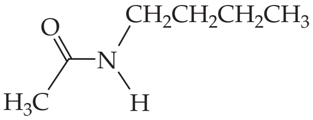
(a)



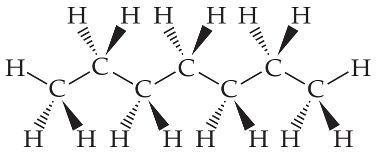
(b)



(c)

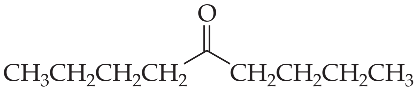


(d)



(e)

(f)



24.45 Draw the molecular structure for **(a)** an aldehyde that is an isomer of acetone, **(b)** an ether that is an isomer of 1-propanol.

24.46 **(a)** Give the empirical formula and structural formula for a cyclic ether containing four carbon atoms in the ring. **(b)** Write the structural formula for a straight-chain compound that is a structural isomer of your answer to part (a).

24.47 The IUPAC name for a carboxylic acid is based on the name of the hydrocarbon with the same number of carbon atoms. The ending *-oic* is appended, as in ethanoic acid, which is the IUPAC name for acetic acid. Draw the structure of the following acids: **(a)** methanoic acid, **(b)** pentanoic acid, **(c)** 2-chloro-3-methyldecanoic acid.

24.48 Aldehydes and ketones can be named in a systematic way by counting the number of carbon atoms (including the carbonyl carbon) that they contain. The name of the aldehyde or ketone is based on the hydrocarbon with the same number of carbon atoms. The ending *-al* for aldehyde or *-one* for ketone is added as appropriate. Draw the structural formulas for the following aldehydes or ketones: **(a)** propanal, **(b)** 2-pentanone, **(c)** 3-methyl-2-butanone, **(d)** 2-methylbutanal.

24.49 Draw the condensed structure of the compounds formed by condensation reactions between **(a)** benzoic acid and ethanol, **(b)** ethanoic acid and methylamine, **(c)** acetic acid and phenol. Name the compound in each case.

24.50 Draw the condensed structures of the compounds formed from **(a)** butanoic acid and methanol, **(b)** benzoic acid and 2-propanol, **(c)** propanoic acid and dimethylamine. Name the compound in each case.

24.51 Write a balanced chemical equation using condensed structural formulas for the saponification (base hydrolysis) of **(a)** methyl propionate, **(b)** phenyl acetate.

24.52 Write a balanced chemical equation using condensed structural formulas for **(a)** the formation of butyl propionate from the appropriate acid and alcohol, **(b)** the saponification (base hydrolysis) of methyl benzoate.

24.53 Pure acetic acid is a viscous liquid, with high melting and boiling points (16.7 °C and 118 °C) compared to compounds of similar molecular weight. Suggest an explanation.

24.54 *Acetic anhydride* is formed from two acetic acid molecules, in a condensation reaction that involves the removal of a molecule of water. Write the chemical equation for this process, and show the structure of acetic anhydride.

24.55 Write the condensed structural formula for each of the following compounds: **(a)** 2-pentanol, **(b)** 1,2-propanediol, **(c)** ethyl acetate, **(d)** diphenyl ketone, **(e)** methyl ethyl ether.

24.56 Write the condensed structural formula for each of the following compounds: **(a)** 2-ethyl-1-hexanol, **(b)** methyl phenyl ketone, **(c)** *para*-bromobenzoic acid, **(d)** ethyl butyl ether, **(e)** *N, N*-dimethylbenzamide.

24.57 How many chiral carbons are in 2-bromo-2-chloro-3-methylpentane? **(a)** 0, **(b)** 1, **(c)** 2, **(d)** 3, **(e)** 4 or more.

24.58 Does 3-chloro-3-methylhexane have optical isomers? Why or why not?

Introduction to Biochemistry; Proteins (Sections 24.6 and 24.7)

24.59 **(a)** Draw the chemical structure of a generic amino acid, using R for the side chain. **(b)** When amino acids react to form proteins, do they do so via substitution, addition, or condensation reactions? **(c)** Draw the bond that links amino acids together in proteins. What is this called?

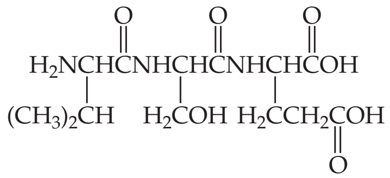
24.60 Indicate whether each statement is true or false. **(a)** Tryptophan is an aromatic amino acid. **(b)** Lysine is positively charged at pH 7. **(c)** Asparagine has two amide bonds. **(d)** Isoleucine and leucine are enantiomers. **(e)** Valine is probably more water-soluble than arginine.

24.61 Draw the two possible dipeptides formed by condensation reactions between histidine and aspartic acid.

24.62 Write a chemical equation for the formation of methionyl glycine from the constituent amino acids.

24.63 **(a)** Draw the condensed structure of the tripeptide Gly-Gly-His. **(b)** How many different tripeptides can be made from the amino acids glycine and histidine? Give the abbreviations for each of these tripeptides, using the three-letter and one-letter codes for the amino acids.

24.64 **(a)** What amino acids would be obtained by hydrolysis of the following tripeptide?



$$H_2N\underset{(CH_3)_2CH}{\underset{|}{CH}}\overset{O}{\overset{\|}{C}}NH\underset{H_2COH}{\underset{|}{CH}}\overset{O}{\overset{\|}{C}}NH\underset{H_2CCH_2\underset{\underset{O}{\|}}{C}OH}{\underset{|}{CH}}\overset{O}{\overset{\|}{C}}OH$$

(b) How many different tripeptides can be made from glycine, serine, and glutamic acid? Give the abbreviation for each of these tripeptides, using the three-letter codes and one-letter codes for the amino acids.

24.65 Indicate whether each statement is true or false. **(a)** The sequence of amino acids in a protein, from the amine end to the acid end, is called the primary structure of the protein. **(b)** Alpha helix and beta sheet structures are examples of quaternary protein structure. **(c)** It is impossible for more than one protein to bind to another and make a higher order structure.

24.66 Indicate whether each statement is true or false: **(a)** In the alpha helical structure of proteins, hydrogen bonding occurs between the side chains (R groups). **(b)** Dispersion forces, not hydrogen bonding, holds beta sheet structures together.

Carbohydrates and Lipids (Sections 24.8 and 24.9)

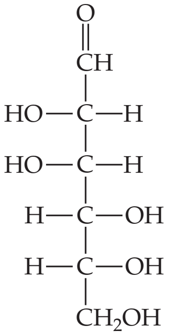
24.67 Indicate whether each statement is true or false: **(a)** Disaccharides are a type of carbohydrate. **(b)** Sucrose is a monosaccharide. **(c)** All carbohydrates have the formula $C_nH_{2m}O_m$.

24.68 **(a)** Are α-glucose and β-glucose enantiomers? **(b)** Show the condensation of two glucose molecules to form a disaccharide with an α linkage. **(c)** Repeat part (b) but with a β linkage.

24.69 **(a)** What is the empirical formula of cellulose? **(b)** What is the monomer that forms the basis of the cellulose polymer? **(c)** What bond connects the monomer units in cellulose: amide, acid, ether, ester, or alcohol?

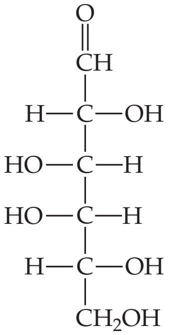
24.70 **(a)** What is the empirical formula of starch? **(b)** What is the monomer that forms the basis of the starch polymer? **(c)** What bond connects the monomer units in starch: amide, acid, ether, ester, or alcohol?

24.71 The structural formula for the linear form of D-mannose is



(**a**) Is this molecule a sugar? (**b**) How many chiral carbons are present in the molecule? (**c**) Draw the structure of the six-member-ring form of this molecule.

24.72 The structural formula for the linear form of galactose is



(**a**) Is this molecule a sugar? (**b**) How many chiral carbons are present in the molecule? (**c**) Draw the structure of the six-member-ring form of this molecule.

24.73 Indicate whether each statement is true or false: (**a**) Fat molecules contain amide bonds. (**b**) Phosphoplipids can be zwitterions. (**c**) Phospholipids form bilayers in water in order to have their long hydrophobic tails interact favorably with each other, leaving their polar heads to the aqueous environment.

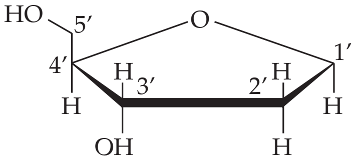
24.74 Indicate whether each statement is true or false: (**a**) If you use data from Table 8.4 on bond enthalpies, you can show that the more C—H bonds a molecule has compared to C—O and O—H bonds, the more energy it can store. (**b**) Trans fats are saturated. (**c**) Fatty acids are long-chain carboxylic acids. (**d**) Monounsaturated fatty acids have one CC single bond in the chain, while the rest are double or triple bonds.

Nucleic Acids (Section 24.10)

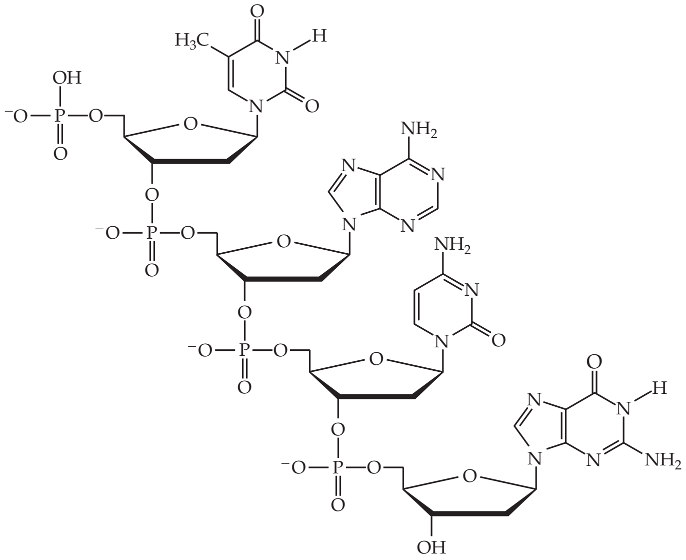
24.75 Adenine and guanine are members of a class of molecules known as *purines*; they have two rings in their structure. Thymine and cytosine, on the other hand, are *pyrimidines*, and have only one ring in their structure. Predict which have larger dispersion forces in aqueous solution, the purines or the pyrimidines.

24.76 A nucleoside consists of an organic base of the kind shown in Section 24.10, bound to ribose or deoxyribose. Draw the structure for deoxyguanosine, formed from guanine and deoxyribose.

24.77 Just as the amino acids in a protein are listed in the order from the amine end to the carboxylic acid end (the primary structure or *protein sequence*), the bases in nucleic acids are listed in the order 5′ to 3′, where the numbers refer to the position of the carbons in the sugars (shown here for deoxyribose):



The base is attached to the sugar at the 1′ carbon. The 5′ end of a DNA sequence is a phosphate of an OH group, and the 3′ end of a DNA sequence is the OH group. What is the DNA sequence for the molecule shown here?



24.78 When samples of double-stranded DNA are analyzed, the quantity of adenine present equals that of thymine. Similarly, the quantity of guanine equals that of cytosine. Explain the significance of these observations.

24.79 Imagine a single DNA strand containing a section with the following base sequence: 5′-GCATTGGC-3′. What is the base sequence of the complementary strand? (The two strands of DNA will come together in an *antiparallel* fashion; that is, 5′-TAG-3′ will bind to 3′-ATC-5′.)

24.80 Which statement best explains the chemical differences between DNA and RNA? (**a**) DNA has two different sugars in its sugar–phosphate backbone, but RNA only has one. (**b**) Thymine is one of the DNA bases, whereas RNA's corresponding base is thymine minus a methyl group. (**c**) The RNA sugar–phosphate backbone contains fewer oxygen atoms than DNA's backbone. (**d**) DNA forms double helices but RNA cannot.

Additional Exercises

24.81 Draw the condensed structural formulas for two different molecules with the formula C_3H_4O.

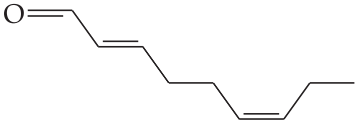
24.82 How many structural isomers are there for a five-member straight carbon chain with one double bond? For a six-member straight carbon chain with two double bonds?

24.83 (**a**) Draw the condensed structural formulas for the cis and trans isomers of 2-pentene. (**b**) Can cyclopentene exhibit cis–trans isomerism? Explain. (**c**) Does 1-pentyne have enantiomers? Explain.

24.84 If a molecule is an "ene-one," what functional groups must it have?

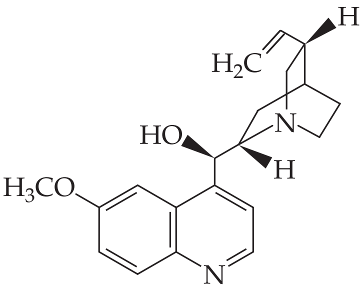
24.85 Identify each of the functional groups in these molecules:

(a)



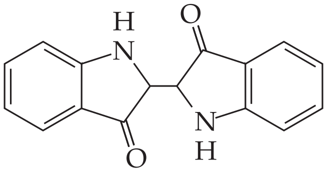
(Responsible for the odor of cucumbers)

(b)



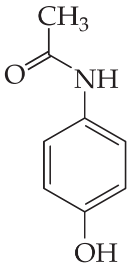
(Quinine — an antimalarial drug)

(c)



(Indigo — a blue dye)

(d)



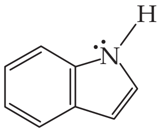
(Acetaminophen — aka Tylenol)

24.86 For the molecules shown in 24.85, (**a**) Which one(s) of them, if any, would produce a basic solution if dissolved in water? (**b**) Which one(s) of them, if any, would produce an acidic solution if dissolved in water? (**c**) Which of them is the most water-soluble?

24.87 Write a condensed structural formula for each of the following: **(a)** an acid with the formula $C_4H_8O_2$, **(b)** a cyclic ketone with the formula C_5H_8O, **(c)** a dihydroxy compound with the formula $C_3H_8O_2$, **(d)** a cyclic ester with the formula $C_5H_8O_2$.

24.88 Carboxylic acids generally have pK_a's of ~5, but alcohols have pK_a's of ~16. (**a**) Write the acid-dissociation chemical equation for the generic alcohol ROH in water. (**b**) Which compounds will produce more acidic solutions upon dissolution in water, acids or alcohols? (**c**) Suggest an explanation for the difference in pK_a's for acids compared to alcohols.

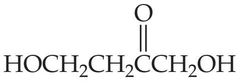
[24.89] Indole smells terrible in high concentrations but has a pleasant floral-like odor when highly diluted. Its structure is



The molecule is planar, and the nitrogen is a very weak base, with $K_b = 2 \times 10^{-12}$. Explain how this information indicates that the indole molecule is aromatic.

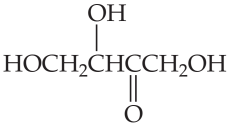
24.90 Locate the chiral carbon atoms, if any, in each molecule:

(a)



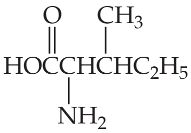
$\mathrm{HOCH_2CH_2\overset{O}{\overset{\|}{C}}CH_2OH}$

(b)



$\mathrm{HOCH_2\overset{OH}{\overset{|}{C}}H\underset{O}{\underset{\|}{C}}CH_2OH}$

(c)



$\mathrm{HO\overset{O}{\overset{\|}{C}}\underset{NH_2}{\underset{|}{C}}H\overset{CH_3}{\overset{|}{C}}HC_2H_5}$

24.91 Which of the following peptides have a net positive charge at pH 7? **(a)** Gly-Ser-Lys, **(b)** Pro-Leu-Ile, **(c)** Phe-Tyr-Asp.

24.92 Glutathione is a tripeptide found in most living cells. Partial hydrolysis yields Cys-Gly and Glu-Cys. What structures are possible for glutathione?

24.93 Monosaccharides can be categorized in terms of the number of carbon atoms (pentoses have five carbons and hexoses have six carbons) and according to whether they contain an aldehyde (*aldo*- prefix, as in aldopentose) or ketone group (*keto*- prefix, as in ketopentose). Classify glucose and fructose in this way.

24.94 Can a DNA strand bind to a complementary RNA strand? Explain.

Integrative Exercises

24.95 Explain why the boiling point of ethanol (78 °C) is much higher than that of its isomer, dimethyl ether (−25 °C), and why the boiling point of CH_2F_2 (−52 °C) is far above that of CH_4 (−128 °C).

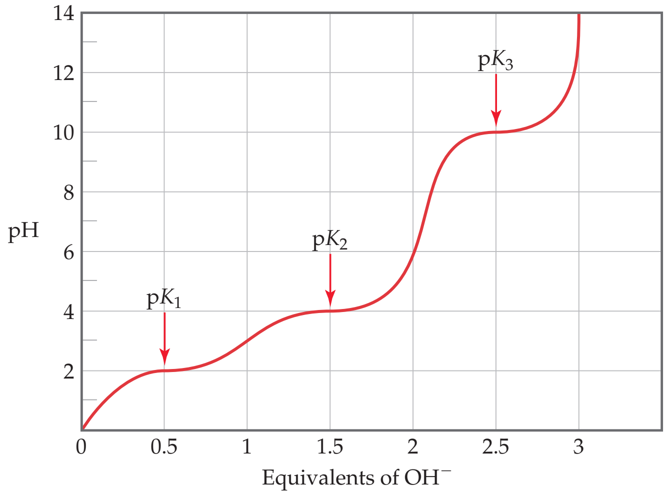
[24.96] An unknown organic compound is found on elemental analysis to contain 68.1% carbon, 13.7% hydrogen, and 18.2% oxygen by mass. It is slightly soluble in water. Upon careful oxidation it is converted into a compound that behaves chemically like a ketone and contains 69.7% carbon, 11.7% hydrogen, and 18.6% oxygen by mass. Indicate two or more reasonable structures for the unknown.

24.97 An organic compound is analyzed and found to contain 66.7% carbon, 11.2% hydrogen, and 22.1% oxygen by mass. The compound boils at 79.6 °C. At 100 °C and 0.970 atm, the vapor has a density of 2.28 g/L. The compound has a carbonyl group and cannot be oxidized to a carboxylic acid. Suggest a structure for the compound.

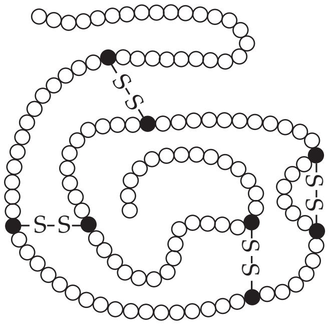
24.98 An unknown substance is found to contain only carbon and hydrogen. It is a liquid that boils at 49 °C at 1 atm pressure. Upon analysis it is found to contain 85.7% carbon and 14.3% hydrogen by mass. At 100 °C and 735 torr, the vapor of this unknown has a density of 2.21 g/L. When it is dissolved in hexane solution and bromine water is added, no reaction occurs. What is the identity of the unknown compound?

24.99 The standard free energy of formation of solid glycine is −369 kJ/mol, whereas that of solid glycylglycine is −488 kJ/mol. What is ΔG° for the condensation of glycine to form glycylglycine?

24.100 A typical amino acid with one amino group and one carboxylic acid group, such as serine, can exist in water in several ionic forms. **(a)** Suggest the forms of the amino acid at low pH and at high pH. **(b)** Amino acids generally have two pK_a values, one in the range of 2 to 3 and the other in the range of 9 to 10. Serine, for example, has pK_a values of 2.19 and 9.21. Using species such as acetic acid and ammonia as models, suggest the origin of the two pK_a values. **(c)** Glutamic acid is an amino acid that has three pK_a's: 2.10, 4.07, and 9.47. Draw the structure of glutamic acid, and assign each pK_a to the appropriate part of the molecule. **(d)** An unknown amino acid is titrated with strong base, producing the following titration curve. Which amino acids are likely candidates for the unknown?



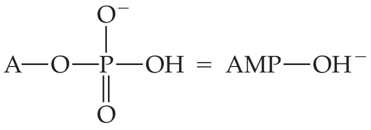
[24.101] The protein ribonuclease A in its native, or most stable, form is folded into a compact globular shape:



Native ribonuclease A

(a) Does the native form have a lower or higher free energy than the denatured form, in which the protein is an extended chain? **(b)** What is the sign of the system's entropy change in going from the denatured to the folded form? **(c)** In the native form, the molecule has four —S—S— bonds that bridge parts of the chain. What effect do you predict these four linkages to have on the free energy and entropy of the native form relative to the free energy and entropy of a hypothetical folded structure that does not have any —S—S— linkages? Explain. **(d)** A gentle reducing agent converts the four —S—S— linkages in ribonuclease A to eight —S—H bonds. What effect do you predict this conversion to have on the tertiary structure and entropy of the protein? **(e)** Which amino acid must be present for —SH bonds to exist in ribonuclease A?

24.102 The monoanion of adenosine monophosphate (AMP) is an intermediate in phosphate metabolism:



$$\mathrm{A{-}O{-}}\overset{\displaystyle O^-}{\overset{|}{\underset{\underset{\displaystyle O}{\|}}{P}}}\mathrm{{-}OH} = \mathrm{AMP{-}OH^-}$$

where A = adenosine. If the pK_a for this anion is 7.21, what is the ratio of $[AMP{-}OH^-]$ to $[AMP{-}O^{2-}]$ in blood at pH 7.4?

Design an Experiment

Quaternary structures of proteins arise if two or more smaller polypeptides or proteins associate with each other to make a much larger protein structure. The association is due to the same hydrogen bonding, electrostatic, and dispersion forces we have seen before. Hemoglobin, the protein used to transport oxygen molecules in our blood, is an example of a protein that has quaternary structure. Hemoglobin is a tetramer; it is made of four smaller polypeptides, two "alphas" and two "betas." (These names do not imply anything about the number of alpha-helices or beta sheets in the individual polypeptides.) Design a set of experiments that would provide sound evidence that hemoglobin exists as a tetramer and not as one enormous polypeptide chain.

APPENDIX

A

Mathematical Operations

A.1 | Exponential Notation

The numbers used in chemistry are often either extremely large or extremely small. Such numbers are conveniently expressed in the form

$$N \times 10^n$$

where N is a number between 1 and 10, and n is the exponent. Some examples of this *exponential notation*, which is also called *scientific notation*, follow.

1,200,000 is 1.2×10^6 (read “one point two multi ten to the sixth power”)

0.000604 is 6.04×10^{-4} (read “six point zero four times ten to the negative fourth power”)

A positive exponent, as in the first example, tells us how many times a number must be multiplied by 10 to give the long form of the number:

$$\begin{aligned} 1.2 \times 10^6 &= 1.2 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \quad \text{(six tens)} \\ &= 1{,}200{,}000 \end{aligned}$$

It is also convenient to think of the *positive exponent* as the number of places the decimal point must be moved to the *left* to obtain a number greater than 1 and less than 10. For example, if we begin with 3450 and move the decimal point three places to the left, we end up with 3.45×10^3.

In a related fashion, a negative exponent tells us how many times we must divide a number by 10 to give the long form of the number.

$$6.04 \times 10^{-4} = \frac{6.04}{10 \times 10 \times 10 \times 10} = 0.000604$$

It is convenient to think of the *negative exponent* as the number of places the decimal point must be moved to the *right* to obtain a number greater than 1 but less than 10. For example, if we begin with 0.0048 and move the decimal point three places to the right, we end up with 4.8×10^{-3}.

In the system of exponential notation, with each shift of the decimal point one place to the right, the exponent *decreases* by 1:

$$4.8 \times 10^{-3} = 48 \times 10^{-4}$$

Similarly, with each shift of the decimal point one place to the left, the exponent *increases* by 1:

$$4.8 \times 10^{-3} = 0.48 \times 10^{-2}$$

Many scientific calculators have a key labeled EXP or EE, which is used to enter numbers in exponential notation. To enter the number 5.8×10^3 on such a calculator, the key sequence is

$$\boxed{5}\,\boxed{\cdot}\,\boxed{8}\,\boxed{\text{EXP}}\ (\text{or } \boxed{\text{EE}})\,\boxed{3}$$

On some calculators the display will show 5.8, then a space, followed by 03, the exponent. On other calculators, a small 10 is shown with an exponent 3.

To enter a negative exponent, use the key labeled $+/-$. For example, to enter the number 8.6×10^{-5}, the key sequence is

$$\boxed{8}\,\boxed{\cdot}\,\boxed{6}\,\boxed{\text{EXP}}\,\boxed{+/-}\,\boxed{5}$$

When entering a number in exponential notation, do not key in the 10 if you use the EXP or EE button.

In working with exponents, it is important to recall that $10^0 = 1$. The following rules are useful for carrying exponents through calculations.

1. **Addition and Subtraction** In order to add or subtract numbers expressed in exponential notation, the powers of 10 must be the same.

$$\begin{aligned}(5.22 \times 10^4) + (3.21 \times 10^2) &= (522 \times 10^2) + (3.21 \times 10^2)\\ &= 525 \times 10^2 \quad \text{(3 significant figures)}\\ &= 5.25 \times 10^4\\ (6.25 \times 10^{-2}) - (5.77 \times 10^{-3}) &= (6.25 \times 10^{-2}) - (0.577 \times 10^{-2})\\ &= 5.67 \times 10^{-2} \quad \text{(3 significant figures)}\end{aligned}$$

When you use a calculator to add or subtract, you need not be concerned with having numbers with the same exponents because the calculator automatically takes care of this matter.

2. **Multiplication and Division** When numbers expressed in exponential notation are multiplied, the exponents are added; when numbers expressed in exponential notation are divided, the exponent of the denominator is subtracted from the exponent of the numerator.

$$\begin{aligned}(5.4 \times 10^2)(2.1 \times 10^3) &= (5.4)(2.1) \times 10^{2+3}\\ &= 11 \times 10^5\\ &= 1.1 \times 10^6\\ (1.2 \times 10^5)(3.22 \times 10^{-3}) &= (1.2)(3.22) \times 10^{5+(-3)} = 3.9 \times 10^2\\ \frac{3.2 \times 10^5}{6.5 \times 10^2} &= \frac{3.2}{6.5} \times 10^{5-2} = 0.49 \times 10^3 = 4.9 \times 10^2\\ \frac{5.7 \times 10^7}{8.5 \times 10^{-2}} &= \frac{5.7}{8.5} \times 10^{7-(-2)} = 0.67 \times 10^9 = 6.7 \times 10^8\end{aligned}$$

3. **Powers and Roots** When numbers expressed in exponential notation are raised to a power, the exponents are multiplied by the power. When the roots of numbers expressed in exponential notation are taken, the exponents are divided by the root.

$$\begin{aligned}(1.2 \times 10^5)^3 &= (1.2)^3 \times 10^{5\times 3}\\ &= 1.7 \times 10^{15}\\ \sqrt[3]{2.5 \times 10^6} &= \sqrt[3]{2.5} \times 10^{6/3}\\ &= 1.3 \times 10^2\end{aligned}$$

Scientific calculators usually have keys labeled x^2 and $\sqrt{x}$ for squaring and taking the square root of a number, respectively. To take higher powers or roots, many calculators have y^x and $\sqrt[x]{y}$ (or INV y^x) keys. For example, to perform the operation $\sqrt[3]{7.5 \times 10^{-4}}$ on such a calculator, you would key in 7.5×10^{-4}, press the $\sqrt[x]{y}$ key (or the INV and then the y^x keys), enter the root, 3, and finally press $=$. The result is 9.1×10^{-2}.

SAMPLE EXERCISE 1 Using Exponential Notation

Perform each of the following operations, using your calculator where possible:

(a) Write the number 0.0054 in standard exponential notation.
(b) $(5.0 \times 10^{-2}) + (4.7 \times 10^{-3})$
(c) $(5.98 \times 10^{12})(2.77 \times 10^{-5})$
(d) $\sqrt[4]{1.75 \times 10^{-12}}$

SOLUTION

(a) Because we move the decimal point three places to the right to convert 0.0054 to 5.4, the exponent is -3:

$$5.4 \times 10^{-3}$$

Scientific calculators are generally able to convert numbers to exponential notation using one or two keystrokes; frequently "SCI" for "scientific notation" will convert a number into exponential notation. Consult your instruction manual to see how this operation is accomplished on your calculator.

(b) To add these numbers longhand, we must convert them to the same exponent.

$$(5.0 \times 10^{-2}) + (0.47 \times 10^{-2}) = (5.0 + 0.47) \times 10^{-2} = 5.5 \times 10^{-2}$$

(c) Performing this operation longhand, we have

$$(5.98 \times 2.77) \times 10^{12-5} = 16.6 \times 10^{7} = 1.66 \times 10^{8}$$

(d) To perform this operation on a calculator, we enter the number, press the $\sqrt[x]{y}$ key (or the INV and y^x keys), enter 4, and press the = key. The result is 1.15×10^{-3}.

Practice Exercise

Perform the following operations:
(a) Write 67,000 in exponential notation, showing two significant figures.
(b) $(3.378 \times 10^{-3}) - (4.97 \times 10^{-5})$
(c) $(1.84 \times 10^{15})(7.45 \times 10^{-2})$
(d) $(6.67 \times 10^{-8})^3$

A.2 | Logarithms

Common Logarithms

The common, or base-10, logarithm (abbreviated log) of any number is the power to which 10 must be raised to equal the number. For example, the common logarithm of 1000 (written log 1000) is 3 because raising 10 to the third power gives 1000.

$$10^3 = 1000, \text{ therefore, } \log 1000 = 3$$

Further examples are

$$\log 10^5 = 5$$

$$\log 1 = 0 \quad \text{Remember that } 10^0 = 1$$

$$\log 10^{-2} = -2$$

In these examples the common logarithm can be obtained by inspection. However, it is not possible to obtain the logarithm of a number such as 31.25 by inspection. The logarithm of 31.25 is the number x that satisfies the following relationship:

$$10^x = 31.25$$

Most electronic calculators have a key labeled LOG that can be used to obtain logarithms. For example, on many calculators we obtain the value of log 31.25 by entering 31.25 and pressing the LOG key. We obtain the following result:

$$\log 31.25 = 1.4949$$

Notice that 31.25 is greater than 10 (10^1) and less than 100 (10^2). The value for log 31.25 is accordingly between log 10 and log 100, that is, between 1 and 2.

Significant Figures and Common Logarithms

For the common logarithm of a measured quantity, the number of digits after the decimal point equals the number of significant figures in the original number. For example, if 23.5 is a measured quantity (three significant figures), then $\log 23.5 = 1.371$ (three significant figures after the decimal point).

Antilogarithms

The process of determining the number that corresponds to a certain logarithm is known as obtaining an *antilogarithm*. It is the reverse of taking a logarithm. For example, we saw previously that log 23.5 = 1.371. This means that the antilogarithm of 1.371 equals 23.5.

$$\log 23.5 = 1.371$$
$$\text{antilog } 1.371 = 23.5$$

The process of taking the antilog of a number is the same as raising 10 to a power equal to that number.

$$\text{antilog } 1.371 = 10^{1.371} = 23.5$$

Many calculators have a key labeled 10^x that allows you to obtain antilogs directly. On others, it will be necessary to press a key labeled INV (for *inverse*), followed by the LOG key.

Natural Logarithms

Logarithms based on the number e are called natural, or base e, logarithms (abbreviated ln). The natural log of a number is the power to which e (which has the value 2.71828...) must be raised to equal the number. For example, the natural log of 10 equals 2.303.

$$e^{2.303} = 10, \text{ therefore } \ln 10 = 2.303$$

Your calculator probably has a key labeled LN that allows you to obtain natural logarithms. For example, to obtain the natural log of 46.8, you enter 46.8 and press the LN key.

$$\ln 46.8 = 3.846$$

The natural antilog of a number is e raised to a power equal to that number. If your calculator can calculate natural logs, it will also be able to calculate natural antilogs. On some calculators there is a key labeled e^x that allows you to calculate natural antilogs directly; on others, it will be necessary to first press the INV key followed by the LN key. For example, the natural antilog of 1.679 is given by

$$\text{Natural antilog } 1.679 = e^{1.679} = 5.36$$

The relation between common and natural logarithms is as follows:

$$\ln a = 2.303 \log a$$

Notice that the factor relating the two, 2.303, is the natural log of 10, which we calculated earlier.

Mathematical Operations Using Logarithms

Because logarithms are exponents, mathematical operations involving logarithms follow the rules for the use of exponents. For example, the product of z^a and z^b (where z is any number) is given by

$$z^a \cdot z^b = z^{(a+b)}$$

Similarly, the logarithm (either common or natural) of a product equals the *sum* of the logs of the individual numbers.

$$\log ab = \log a + \log b \qquad \ln ab = \ln a + \ln b$$

For the log of a quotient,

$$\log(a/b) = \log a - \log b \qquad \ln(a/b) = \ln a - \ln b$$

Using the properties of exponents, we can also derive the rules for the logarithm of a number raised to a certain power.

$$\log a^n = n \log a \qquad \ln a^n = n \ln a$$

$$\log a^{1/n} = (1/n)\log a \quad \ln a^{1/n} = (1/n)\ln a$$

pH Problems

One of the most frequent uses for common logarithms in general chemistry is in working pH problems. The pH is defined as $-\log[\mathrm{H}^+]$, where $[\mathrm{H}^+]$ is the hydrogen ion concentration of a solution. (Section 16.4) The following sample exercise illustrates this application.

SAMPLE EXERCISE 2 Using Logarithms

(a) What is the pH of a solution whose hydrogen ion concentration is 0.015 *M*?
(b) If the pH of a solution is 3.80, what is its hydrogen ion concentration?

SOLUTION

(1) We are given the value of $[\mathrm{H}^+]$. We use the LOG key of our calculator to calculate the value of $\log[\mathrm{H}^+]$. The pH is obtained by changing the sign of the value obtained. (Be sure to change the sign *after* taking the logarithm.)

$$[\mathrm{H}^+] = 0.015$$
$$\log[\mathrm{H}^+] = -1.82 \quad \text{(2 significant figures)}$$
$$\mathrm{pH} = -(-1.82) = 1.82$$

(2) To obtain the hydrogen ion concentration when given the pH, we must take the antilog of $-$pH.

$$\mathrm{pH} = -\log[\mathrm{H}^+] = 3.80$$
$$\log[\mathrm{H}^+] = -3.80$$
$$[\mathrm{H}^+] = \text{antilog}(-3.80) = 10^{-3.80} = 1.6 \times 10^{-4}\ M$$

Practice Exercise

Perform the following operations: **(a)** $\log(2.5 \times 10^{-5})$, **(b)** ln 32.7, **(c)** antilog -3.47, **(d)** $e^{-1.89}$.

A.3 | Quadratic Equations

An algebraic equation of the form $ax^2 + bx + c = 0$ is called a *quadratic equation*. The two solutions to such an equation are given by the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Many calculators today can calculate the solutions to a quadratic equation with one or two keystrokes. Most of the time, x corresponds to the concentration of a chemical species in solution. Only one of the solutions will be a positive number, and that is the one you should use; a "negative concentration" has no physical meaning.

SAMPLE EXERCISE 3 Using the Quadratic Formula

Find the values of x that satisfy the equation $2x^2 + 4x = 1$.

SOLUTION

To solve the given equation for x, we must first put it in the form

$$ax^2 + bx + c = 0$$

and then use the quadratic formula. If

$$2x^2 + 4x = 1$$

then

$$2x^2 + 4x - 1 = 0$$

Using the quadratic formula, where $a = 2$, $b = 4$, and $c = -1$, we have

$$x = \frac{-4 \pm \sqrt{4^2 - 4(2)(-1)}}{2(2)}$$
$$= \frac{-4 \pm \sqrt{16 + 8}}{4} = \frac{-4 \pm \sqrt{24}}{4} = \frac{-4 \pm 4.899}{4}$$

The two solutions are

$$x = \frac{0.899}{4} = 0.225 \quad \text{and} \quad x = \frac{-8.899}{4} = -2.225$$

If this was a problem in which x represented a concentration, we would say $x = 0.225$ (in the appropriate units), since a negative number for concentration has no physical meaning.

A.4 | Graphs

Often the clearest way to represent the interrelationship between two variables is to graph them. Usually, the variable that is being experimentally varied, called the *independent variable*, is shown along the horizontal axis (x-axis). The variable that responds to the change in the independent variable, called the *dependent variable*, is then shown along the vertical axis (y-axis). For example, consider an experiment in which we vary the temperature of an enclosed gas and measure its pressure. The independent variable is temperature and the dependent variable is pressure. The data shown in ▶ **Table A.1** can be obtained by means of this experiment. These data are shown graphically in ▶ **Figure A.1**. The relationship between temperature and pressure is linear. The equation for any straight-line graph has the form

$$y = mx + b$$

where m is the slope of the line and b is the intercept with the y-axis. In the case of Figure A.1, we could say that the relationship between temperature and pressure takes the form

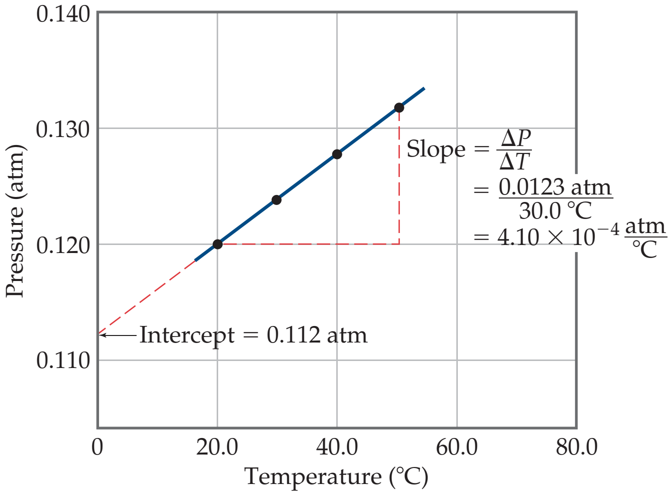
$$P = mT + b$$

where P is pressure in atm and T is temperature in °C. As shown in Figure A.1, the slope is 4.10×10^{-4} atm/°C, and the intercept—the point where the line crosses the y-axis—is 0.112 atm. Therefore, the equation for the line is

$$P = \left(4.10 \times 10^{-4} \frac{\text{atm}}{°\text{C}}\right)T + 0.112 \text{ atm}$$

Table A.1 Interrelation between Pressure and Temperature

Temperature (°C)	Pressure (atm)
20.0	0.120
30.0	0.124
40.0	0.128
50.0	0.132



▲ **Figure A.1** A graph of pressure versus temperature yields a straight line for the data.

A.5 | Standard Deviation

The standard deviation from the mean, s, is a common method for describing precision in experimentally determined data. We define the standard deviation as

$$s = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \overline{x})^2}{N - 1}}$$

where N is the number of measurements, $\overline{x}$ is the average (also called the mean) of the measurements, and *xi* represent the individual measurements. Electronic calculators with built-in statistical functions can calculate s directly by inputting the individual measurements.

A smaller value of s indicates a higher precision, meaning that the data are more closely clustered around the average. The standard deviation has statistical significance. If a large number of measurements is made, 68% of the measured values is expected to be within one standard deviation of the average, assuming only random errors are associated with the measurements.

SAMPLE EXERCISE 4 Calculating an Average and Standard Deviation

The percent carbon in a sugar is measured four times: 42.01%, 42.28%, 41.79%, and 42.25%. Calculate **(a)** the average and **(b)** the standard deviation for these measurements.

SOLUTION

(a) The average is found by adding the quantities and dividing by the number of measurements:

$$\overline{x} = \frac{42.01 + 42.28 + 41.79 + 42.25}{4} = \frac{168.33}{4} = 42.08$$

(b) The standard deviation is found using the preceding equation:

$$s = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \bar{x})^2}{N - 1}}$$

Let's tabulate the data so the calculation of $\sum_{i=1}^{N}(x_i - \bar{x})^2$ can be seen clearly.

Percent C	Difference between Measurement and Average, $(x_i - \bar{x})$	Square of Difference, $(x_i - x)^2$
42.01	$42.01 - 42.08 = -0.07$	$(-0.07)^2 = 0.005$
42.28	$42.28 - 42.08 = 0.20$	$(0.20)^2 = 0.040$
41.79	$41.79 - 42.08 = -0.29$	$(-0.29)^2 = 0.084$
42.25	$42.25 - 42.08 = 0.17$	$(0.17)^2 = 0.029$

The sum of the quantities in the last column is

$$\sum_{i=1}^{N}(x_i - \bar{x})^2 = 0.005 + 0.040 + 0.084 + 0.029 = 0.16$$

Thus, the standard deviation is

$$s = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \bar{x})^2}{N - 1}} = \sqrt{\frac{0.16}{4 - 1}} = \sqrt{\frac{0.16}{3}} = \sqrt{0.053} = 0.23$$

Based on these measurements, it would be appropriate to represent the measured percent carbon as 42.08 ± 0.23.

D

Aqueous Equilibrium Constants

Table D.1 Dissociation Constants for Acids at 25 °C

Name	Formula	K_{a1}	K_{a2}	K_{a3}
Acetic acid	CH_3COOH (or $HC_2H_3O_2$)	1.8×10^{-5}		
Arsenic acid	H_3AsO_4	5.6×10^{-3}	1.0×10^{-7}	3.0×10^{-12}
Arsenous acid	H_3AsO_3	5.1×10^{-10}		
Ascorbic acid	$H_2C_6H_6O_6$	8.0×10^{-5}	1.6×10^{-12}	
Benzoic acid	C_6H_5COOH (or $HC_7H_5O_2$)	6.3×10^{-5}		
Boric acid	H_3BO_3	5.8×10^{-10}		
Butanoic acid	C_3H_7COOH (or $HC_4H_7O_2$)	1.5×10^{-5}		
Carbonic acid	H_2CO_3	4.3×10^{-7}	5.6×10^{-11}	
Chloroacetic acid	$CH_2ClCOOH$ (or $HC_2H_2O_2Cl$)	1.4×10^{-3}		
Chlorous acid	$HClO_2$	1.1×10^{-2}		
Citric acid	$HOOCC(OH)(CH_2COOH)_2$ (or $H_3C_6H_5O_7$)	7.4×10^{-4}	1.7×10^{-5}	4.0×10^{-7}
Cyanic acid	$HCNO$	3.5×10^{-4}		
Formic acid	$HCOOH$ (or $HCHO_2$)	1.8×10^{-4}		
Hydroazoic acid	HN_3	1.9×10^{-5}		
Hydrocyanic acid	HCN	4.9×10^{-10}		
Hydrofluoric acid	HF	6.8×10^{-4}		
Hydrogen chromate ion	$HCrO_4^-$	3.0×10^{-7}		
Hydrogen peroxide	H_2O_2	2.4×10^{-12}		
Hydrogen selenate ion	$HSeO_4^-$	2.2×10^{-2}		
Hydrogen sulfide	H_2S	9.5×10^{-8}	1×10^{-19}	
Hypobromous acid	$HBrO$	2.5×10^{-9}		
Hypochlorous acid	$HClO$	3.0×10^{-8}		
Hypoiodous acid	HIO	2.3×10^{-11}		
Iodic acid	HIO_3	1.7×10^{-1}		
Lactic acid	$CH_3CH(OH)COOH$ (or $HC_3H_5O_3$)	1.4×10^{-4}		
Malonic acid	$CH_2(COOH)_2$ (or $H_2C_3H_2O_4$)	1.5×10^{-3}	2.0×10^{-6}	
Nitrous acid	HNO_2	4.5×10^{-4}		
Oxalic acid	$(COOH)_2$ (or $H_2C_2O_4$)	5.9×10^{-2}	6.4×10^{-5}	
Paraperiodic acid	H_5IO_6	2.8×10^{-2}	5.3×10^{-9}	
Phenol	C_6H_5OH (or HC_6H_5O)	1.3×10^{-10}		
Phosphoric acid	H_3PO_4	7.5×10^{-3}	6.2×10^{-8}	4.2×10^{-13}
Propionic acid	C_2H_5COOH (or $HC_3H_5O_2$)	1.3×10^{-5}		
Pyrophosphoric acid	$H_4P_2O_7$	3.0×10^{-2}	4.4×10^{-3}	2.1×10^{-7}
Selenous acid	H_2SeO_3	2.3×10^{-3}	5.3×10^{-9}	
Sulfuric acid	H_2SO_4	Strong acid	1.2×10^{-2}	
Sulfurous acid	H_2SO_3	1.7×10^{-2}	6.4×10^{-8}	
Tartaric acid	$HOOC(CHOH)_2COOH$ (or $H_2C_4H_4O_6$)	1.0×10^{-3}		

Table D.2 Dissociation Constants for Bases at 25 °C

Name	Formula	K_b
Ammonia	NH_3	1.8×10^{-5}
Aniline	$C_6H_5NH_2$	4.3×10^{-10}
Dimethylamine	$(CH_3)_2NH$	5.4×10^{-4}
Ethylamine	$C_2H_5NH_2$	6.4×10^{-4}
Hydrazine	H_2NNH_2	1.3×10^{-6}
Hydroxylamine	$HONH_2$	1.1×10^{-8}
Methylamine	CH_3NH_2	4.4×10^{-4}
Pyridine	C_5H_5N	1.7×10^{-9}
Trimethylamine	$(CH_3)_3N$	6.4×10^{-5}

Table D.3 Solubility-Product Constants for Compounds at 25 °C

Name	Formula	K_{sp}	Name	Formula	K_{sp}
Barium carbonate	$BaCO_3$	5.0×10^{-9}	Lead(II) fluoride	PbF_2	3.6×10^{-8}
Barium chromate	$BaCrO_4$	2.1×10^{-10}	Lead(II) sulfate	$PbSO_4$	6.3×10^{-7}
Barium fluoride	BaF_2	1.7×10^{-6}	Lead(II) sulfide*	PbS	3×10^{-28}
Barium oxalate	BaC_2O_4	1.6×10^{-6}	Magnesium hydroxide	$Mg(OH)_2$	1.8×10^{-11}
Barium sulfate	$BaSO_4$	1.1×10^{-10}	Magnesium carbonate	$MgCO_3$	3.5×10^{-8}
Cadmium carbonate	$CdCO_3$	1.8×10^{-14}	Magnesium oxalate	MgC_2O_4	8.6×10^{-5}
Cadmium hydroxide	$Cd(OH)_2$	2.5×10^{-14}	Manganese(II) carbonate	$MnCO_3$	5.0×10^{-10}
Cadmium sulfide*	CdS	8×10^{-28}	Manganese(II) hydroxide	$Mn(OH)_2$	1.6×10^{-13}
Calcium carbonate (calcite)	$CaCO_3$	4.5×10^{-9}	Manganese(II) sulfide*	MnS	2×10^{-53}
Calcium chromate	$CaCrO_4$	4.5×10^{-9}	Mercury(I) chloride	Hg_2Cl_2	1.2×10^{-18}
Calcium fluoride	CaF_2	3.9×10^{-11}	Mercury(I) iodide	Hg_2I_2	$1.1 \times 10^{-1.1}$
Calcium hydroxide	$Ca(OH)_2$	6.5×10^{-6}	Mercury(II) sulfide*	HgS	2×10^{-53}
Calcium phosphate	$Ca_3(PO_4)_2$	2.0×10^{-29}	Nickel(II) carbonate	$NiCO_3$	1.3×10^{-7}
Calcium sulfate	$CaSO_4$	2.4×10^{-5}	Nickel(II) hydroxide	$Ni(OH)_2$	6.0×10^{-16}
Chromium(III) hydroxide	$Cr(OH)_3$	6.7×10^{-31}	Nickel(II) sulfide*	NiS	3×10^{-20}
Cobalt(II) carbonate	$CoCO_3$	1.0×10^{-10}	Silver bromate	$AgBrO_3$	5.5×10^{-13}
Cobalt(II) hydroxide	$Co(OH)_2$	1.3×10^{-15}	Silver bromide	$AgBr$	5.0×10^{-13}
Cobalt(II) sulfide*	CoS	5×10^{-22}	Silver carbonate	Ag_2CO_3	8.1×10^{-12}
Copper(I) bromide	$CuBr$	5.3×10^{-9}	Silver chloride	$AgCl$	1.8×10^{-10}
Copper(II) carbonate	$CuCO_3$	2.3×10^{-10}	Silver chromate	Ag_2CrO_4	1.2×10^{-12}
Copper(II) hydroxide	$Cu(OH)_2$	4.8×10^{-20}	Silver iodide	AgI	8.3×10^{-17}
Copper(II) sulfide*	CuS	6×10^{-37}	Silver sulfate	Ag_2SO_4	1.5×10^{-5}
Iron(II) carbonate	$FeCO_3$	2.1×10^{-11}	Silver sulfide*	Ag_2S	6×10^{-51}
Iron(II) hydroxide	$Fe(OH)_2$	7.9×10^{-16}	Strontium carbonate	$SrCO_3$	9.3×10^{-10}
Lanthanum fluoride	LaF_3	2×10^{-19}	Tin(II) sulfide*	SnS	1×10^{-26}
Lanthanum iodate	$La(IO_3)_3$	7.4×10^{-14}	Zinc carbonate	$ZnCO_3$	1.0×10^{-10}
Lead(II) carbonate	$PbCO_3$	7.4×10^{-14}	Zinc hydroxide	$Zn(OH)_2$	3.0×10^{-16}
Lead(II) chloride	$PbCl_2$	1.7×10^{-5}	Zinc oxalate	ZnC_2O_4	2.7×10^{-8}
Lead(II) chromate	$PbCrO_4$	2.8×10^{-13}	Zinc sulfide*	ZnS	2×10^{-25}

*For a solubility equilibrium of the type $MS(s) + H_2O(l) \rightleftharpoons M^{2+}(aq) + HS^-(aq) + OH^-(aq)$

ANSWERS TO SELECTED EXERCISES

Chapter 1

1.1 (a) Pure element: i (b) mixture of elements: v, vi (c) pure compound: iv (d) mixture of an element and a compound: ii, iii **1.3** This kind of separation based on solubility differences is called *extraction*. The insoluble grounds are then separated from the coffee solution by *filtration*. **1.5** (a) The aluminum sphere is lightest, then nickel, then silver. (b) The platinum sphere is smallest, then gold, then lead. **1.7** (a) 7.5 cm; two significant figures (sig figs) (b) 72 mi/hr (inner scale, two significant figures) or 115 km/hr (outer scale, three significant figures) **1.9** Arrange the conversion factor so that the given unit cancels and the desired unit is in the correct position. **1.11** 464 jelly beans. The mass of an average bean has 2 decimal places and 3 sig figs. The number of beans then has 3 sig figs, by the rules for multiplication and division. **1.13** (a) Heterogeneous mixture (b) homogeneous mixture (heterogeneous if there are undissolved particles) (c) pure substance (d) pure substance. **1.15** (a) S (b) Au (c) K (d) Cl (e) Cu (f) uranium (g) nickel (h) sodium (i) aluminum (j) silicon **1.17** C is a compound; it contains both carbon and oxygen. A is a compound; it contains at least carbon and oxygen. B is not defined by the data given; it is probably also a compound because few elements exist as white solids. **1.19** Physical properties: silvery white; lustrous; melting point $= 649\ ^\circ\text{C}$, boiling point $= 1105\ ^\circ\text{C}$; density at $20\ ^\circ\text{C} = 1.738\ \text{g/cm}^3$; pounded into sheets; drawn into wires; good conductor. Chemical properties: burns in air; reacts with Cl_2. **1.21** (a) Chemical (b) physical (c) physical (d) chemical (e) chemical **1.23** (a) Add water to dissolve the sugar; filter this mixture, collecting the sand on the filter paper and the sugar water in the flask. Evaporate water from the flask to recover solid sugar. (b) Allow the mixture to settle so that there are two distinct layers. Carefully pour off most of the top oil layer. After the layers reform, use a dropper to remove any remaining oil. Vinegar is in the original vessel and oil is in a second container. **1.25** (a) 1×10^{-1} (b) 1×10^{-2} (c) 1×10^{-15} (d) 1×10^{-6} (e) 1×10^{6} (f) 1×10^{3} (g) 1×10^{-9} (h) 1×10^{-3} (i) 1×10^{-12} **1.27** (a) 22 °C (b) 422.1 °F (c) 506 K (d) 107 °F (e) 1644 K (f) -459.67 °F **1.29** (a) 1.62 g/mL. Tetrachloroethylene, 1.62 g/mL, is more dense than water, 1.00 g/mL; tetrachloroethylene will sink rather than float on water. (b) 11.7 g **1.31** (a) Calculated density $= 0.86$ g/mL. The substance is probably toluene, density $= 0.866$ g/mL. (b) 40.4 mL ethylene glycol (c) 1.11×10^{3} g nickel **1.33** 32 Pg **1.35** Exact: (b), (d), and (f) **1.37** (a) 3 (b) 2 (c) 5 (d) 3 (e) 5 (f) 1 **1.39** (a) 1.025×10^{2} (b) 6.570×10^{2} (c) 8.543×10^{-3} (d) 2.579×10^{-4} (e) -3.572×10^{-2} **1.41** (a) 17.00 (b) 812.0 (c) 8.23×10^{3} (d) 8.69×10^{-2} **1.43** 5 significant figures

1.45 (a) $\dfrac{1 \times 10^{-3}\ \text{m}}{1\ \text{mm}} \times \dfrac{1\ \text{nm}}{1 \times 10^{-9}\ \text{m}}$ (b) $\dfrac{1 \times 10^{-3}\ \text{g}}{1\ \text{mg}} \times \dfrac{1\ \text{kg}}{1000\ \text{g}}$ (c) $\dfrac{1000\ \text{m}}{1\ \text{km}} \times \dfrac{1\ \text{cm}}{1 \times 10^{-2}\ \text{m}} \times \dfrac{1\ \text{in.}}{2.54\ \text{cm}} \times \dfrac{1\ \text{ft}}{12\ \text{in.}}$ (d) $\dfrac{(2.54)^3\ \text{cm}^3}{1^3\ \text{in.}^3}$

1.47 (a) 54.7 km/hr (b) 1.3×10^{3} gal (c) 46.0 m (d) 0.984 in/hr **1.49** The volume of the box is $1.52 \times 10^{4}\ \text{cm}^3$.The uncertainty in the calculated volume is $\pm 0.4 \times 10^{4}\ \text{cm}^3$ cm. **1.51** (a) 4.32×10^{5} s (b) 88.5 m (c) \$0.499/L (d) 46.6 km/hr (e) 1.420 L/s (f) $707.9\ \text{cm}^3$ **1.53** (a) 1.2×10^{2} L (b) 5×10^{2} mg (c) 19.9 mi/gal (2×10^{1} mi/gal for 1 significant figure) (d) 1.81 kg **1.55** 64 kg air **1.57** \$$6 \times 10^{4}$ **1.61** 8.47 g O; the *law of constant composition* **1.63** (a) Set I, 22.51; set II, 22.61. Based on the average, set I is more accurate. (b) The average deviation for both set I and set II is 0.02. The two sets display the same precision. **1.65** (a) Volume (b) area (c) volume (d) density (e) time (f) length (g) temperature **1.68** Substances (c), (d), (e), (g) and (h) are pure or nearly pure. **1.69** (a) 1.13×10^{5} quarters (b) 6.41×10^{5} g (c) \$$2.83 \times 10^{4}$ (d) 5.74×10^{8} stacks **1.73** The most dense liquid, Hg, will sink; the least dense, cyclohexane, will float; H_2O will be in the middle. **1.76** density of solid $= 1.63$ g/mL **1.79** (a) Density of peat $= 0.13\ \text{g/cm}^3$, density of soil $= 2.5\ \text{g/cm}^3$. It is not correct to say that peat is "lighter" than topsoil. Volumes must be specified in order to compare masses. (b) Buy 16 bags of peat (more than 15 are needed). (Results to 1 significant figure are not meaningful.) **1.83** The inner diameter of the tube is 1.71 cm. **1.85** The separation is successful if two distinct spots are seen on the paper. To quantify the characteristics of the separation, calculate a reference value for each spot: distance traveled by spot/distance traveled by solvent. If the values for the two spots are fairly different, the separation is successful. **1.88** (a) Volume $= 0.050$ mL (b) surface area $= 12.4\ \text{m}^2$ (c) 99.99% of the mercury was removed. (c) The spongy material weighs 17.7 mg after exposure to mercury.

Chapter 2

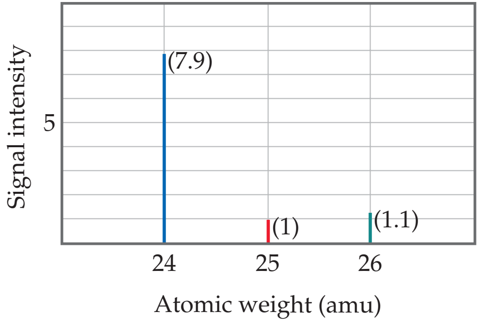
2.1 (a) The path of the charged particle bends because the particle is repelled by the negatively charged plate and attracted to the positively charged plate. (b) $(-)$ (c) increase (d) decrease **2.4** The particle is an ion. ${}^{32}_{16}\text{S}^{2-}$ **2.6** Formula: IF_5; name: iodine pentafluoride; the compound is molecular. **2.8** Only $\text{Ca(NO}_3)_2$, calcium nitrate, is consistent with the diagram. **2.10** (a) In the presence of an electric field, there is electrostatic attraction between the negatively charged oil drops and the positively charged plate as well as electrostatic repulsion between the negatively charged oil drops and the negatively charged plate. These electrostatic forces oppose the force of gravity and change the rate of fall of the drops. (b) Each individual drop has a different number of electrons associated with it. If the combined electrostatic forces are greater than the force of gravity, the drop moves up. **2.11** Postulate 4 of the atomic theory states that the relative number and kinds of atoms in a compound are constant, regardless of the source. Therefore, 1.0 g of pure water should always contain the same relative amounts of hydrogen and oxygen, no matter where or how the sample is obtained. **2.13** (a) 0.5711 g O/1 g N; 1.142 g O/1 g N; 2.284 g O/1 g N; 2.855 g O/1 g N (b) The numbers in part (a) obey the *law of multiple proportions*. Multiple proportions arise because atoms are the indivisible entities combining, as stated in Dalton's atomic theory. **2.15** (i) Electric and magnetic fields deflected the rays in the same way they would deflect negatively charged particles. (ii) A metal plate exposed to cathode rays acquired a negative charge. **2.17** (a) Most of the volume of an atom is empty space in which electrons move. Most alpha particles passed through this space. (b) The few alpha particles that hit the massive, positively charged gold nuclei were strongly repelled and deflected back in the direction they came from. (c) Because the Be nuclei have a smaller volume and a smaller positive charge than the Au nuclei, fewer alpha particles will be scattered and fewer will be strongly back scattered. **2.19** (a) 0.135 nm; 1.35×10^{2} or 135 pm (b) 3.70×10^{6} Au atoms (c) $1.03 \times 10^{-23}\ \text{cm}^3$ **2.21** (a) Proton, neutron, electron (b) proton $= 1+$, neutron $= 0$, electron $= 1-$ (c) The neutron is most massive. (The neutron and proton have very similar masses.) (d) The electron is least massive. **2.23** (a) Not isotopes (b) isotopes (c) isotopes **2.25** (a) Atomic number is the number of protons in the nucleus of an atom. Mass number is the total number of nuclear particles, protons plus neutrons, in an atom. (b) mass number **2.27** (a) ${}^{40}\text{Ar}$: 18 p, 22 n, 18 e (b) ${}^{65}\text{Zn}$: 30 p, 35 n, 30 e (c) ${}^{70}\text{Ga}$: 31 p, 39 n, 31 e (d) ${}^{80}\text{Br}$: 35 p, 45 n, 35 e (e) ${}^{184}\text{W}$: 74 p, 110 n, 74 e (f) ${}^{243}\text{Am}$: 95 p, 148 n, 95e

2.29

Symbol	${}^{79}\text{Br}$	${}^{55}\text{Mn}$	${}^{112}\text{Cd}$	${}^{222}\text{Rn}$	${}^{207}\text{Pb}$
Protons	35	25	48	86	82
Neutrons	44	30	64	136	125
Electrons	35	25	48	86	82
Mass no.	79	55	112	222	207

2.31 (a) $^{196}_{78}Pt$ (b) $^{84}_{36}Kr$ (c) $^{75}_{33}As$ (d) $^{24}_{12}Mg$ **2.33** (a) $^{12}_{6}C$ (b) Atomic weights are average atomic masses, the sum of the mass of each naturally occurring isotope of an element times its fractional abundance. Each B atom will have the mass of one of the naturally occurring isotopes, while the “atomic weight” is an average value. **2.35** 63.55 amu **2.37** (a) In Thomson’s cathode ray tube, the charged particles are electrons. In a mass spectrometer, the charged particles are positively charged ions (cations). (b) The *x*-axis label is atomic weight, and the *y*-axis label is signal intensity. (c) The Cl^{2+} ion will be deflected more. **2.39** (a) average atomic mass = 24.31 amu

(b)

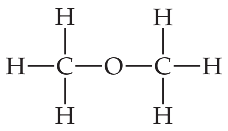


2.41 (a) Cr, 24 (metal) (b) He, 2 (nonmetal) (c) P, 15 (nonmetal) (d) Zn, 30 (metal) (e) Mg, 12 (metal) (f) Br, 35 (nonmetal) (g) As, 33 (metalloid) **2.43** (a) K, alkali metals (metal) (b) I, halogens (nonmetal) (c) Mg, alkaline earth metals (metal) (d) Ar, noble gases (nonmetal) (e) S, chalcogens (nonmetal) **2.45** An empirical formula shows the simplest mole ratio of elements in a compound. A molecular formula shows the exact number and kinds of atoms in a molecule. A structural formula shows which atoms are attached to which. **2.47** From left to right: molecular, N_2H_4, empirical, NH_2; molecular, N_2H_2, empirical, NH, molecular and empirical, NH_3 **2.49** (a) $AlBr_3$ (b) C_4H_5 (c) C_2H_4O (d) P_2O_5 (e) C_3H_2Cl (f) BNH_2 **2.51** (a) 6 (b) 10 (c) 12

2.53

(a)

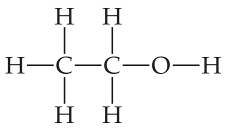
C_2H_6O,



$$H-\underset{H}{\overset{H}{C}}-O-\underset{H}{\overset{H}{C}}-H$$

(b)

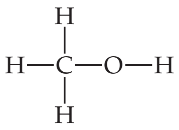
C_2H_6O,



$$H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-O-H$$

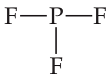
(c)

CH_4O,



$$H-\underset{H}{\overset{H}{C}}-O-H$$

(d) PF_3,



$$F-\underset{F}{P}-F$$

Electrons	24	36	74	78
Net Charge	3+	2−	2+	2+

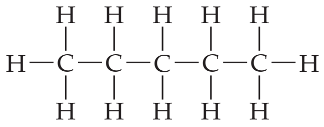
2.57 (a) Mg^{2+} (b) Al^{3+} (c) K^+ (d) S^{2-} (e) F^- **2.59** (a) GaF_3, gallium(III) fluoride (b) LiH, lithium hydride (c) AlI_3, aluminum iodide (d) K_2S, potassium sulfide **2.61** (a) $CaBr_2$ (b) K_2CO_3 (c) $Al(CH_3COO)_3$ (d) $(NH_4)_2SO_4$ (e) $Mg_3(PO_4)_2$

2.63

Ion	K^+	NH_4^+	Mg^{2+}	Fe^{3+}
Cl^-	KCL	NH_4Cl	$MgCl_2$	$FeCl_3$
OH^-	KOH	NH_4OH	$Mg(OH)_2$	$Fe(OH)_3$
CO_3^{2-}	K_2CO_3	$(NH_4)_2CO_3$	$MgCO_3$	$Fe_2(CO_3)_3$
PO_4^{3-}	K_3PO_4	$(NH_4)_3PO_4$	$Mg_3(PO_4)_2$	$FePO_4$

2.65 Molecular: (a) B_2H_6 (b) CH_3OH (f) NOCl (g) NF_3. Ionic: (c) $LiNO_3$ (d) Sc_2O_3 (e) CsBr (f) Ag_2SO_4 **2.67** (a) ClO_2^- (b) Cl^- (c) ClO_3^- (d) ClO_4^- (e) ClO^- **2.69** (a) calcium, 2+; oxide, 2− (b) sodium, 1+; sulfate, 2− (c) potassium, 1+; perchlorate, 1− (d) iron, 2+, nitrate, 1− (e) chromium, 3+; hydroxide, 1− **2.71** (a) lithium oxide (b) iron(III) chloride (ferric chloride) (c) sodium hypochlorite (d) calcium sulfite (e) copper(II) hydroxide (cupric hydroxide) (f) iron(II) nitrate (ferrous nitrate) (g) calcium acetate (h) chromium(III) carbonate (chromic carbonate) (i) potassium chromate (j) ammonium sulfate **2.73** (a) $Al(OH)_3$ (b) K_2SO_4 (c) Cu_2O (d) $Zn(NO_3)_2$ (e) $HgBr_2$ (f) $Fe_2(CO_3)_3$ (g) NaBrO **2.75** (a) Bromic acid (b) hydrobromic acid (c) phosphoric acid (d) HClO (e) HIO_3 (f) H_2SO_3 **2.77** (a) Sulfur hexafluoride (b) iodine pentafluoride (c) xenon trioxide (d) N_2O_4 (e) HCN (f) P_4S_6 **2.79** (a) $ZnCO_3$, ZnO, CO_2 (b) HF, SiO_2, SiF_4, H_2O (c) SO_2, H_2O, H_2SO_3 (d) PH_3 (e) $HClO_4$, Cd, $Cd(ClO_4)_2$ (f) VBr_3 **2.81** (a) A hydrocarbon is a compound composed of the elements hydrogen and carbon only.

(b)

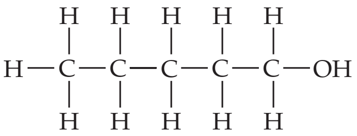


$$H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-H$$

molecular and empirical formulas, C_5H_{12}

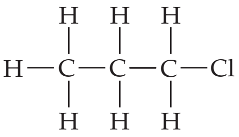
2.83 (a) A functional group is a group of specific atoms that are constant from one molecule to the next. (b) —OH

(c)



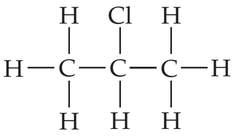
$$H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-OH$$

2.85 (a, b)



$$H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-Cl$$

1-chloropropane



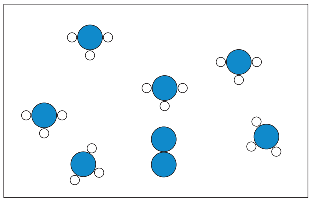
$$H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{Cl}{C}}-\underset{H}{\overset{H}{C}}-H$$

2-chloropropane

2.88 (a) 2 protons, 1 neutron, 2 electrons (b) tritium, ^3H, is more massive. (c) A precision of 1×10^{-27} g would be required to differentiate between $^3H^+$ and $^3He^+$. **2.90** Arrangement A, 4.1×10^{14} atoms/cm^2 (b) Arrangement B, 4.7×10^{14} atoms/cm^2 (c) The ratio of atoms going from arrangement B to arrangement A is 1.2 to 1. In three dimensions, arrangement B leads to a greater density for Rb metal. **2.94** (a) $^{16}_{8}O$, $^{17}_{8}O$, $^{18}_{8}O$ (b) All isotopes are atoms of the same element, oxygen, with the same atomic number, 8 protons in the nucleus and 8 electrons. We expect their electron arrangements to be the same and their chemical properties to be very similar. Each has a different number of neutrons, a different mass number, and a different atomic mass. **2.96** (a) $^{69}_{31}Ga$, 31 protons, 38 neutrons; $^{71}_{31}Ga$, 31 protons, 40 neutrons (b) $^{69}_{31}Ga$, 60.3%, $^{71}_{31}Ga$, 39.7%. **2.99** (a) 5 significant figures (b) An electron is 0.05444% of the mass of an ^1H atom. **2.104** (a) nickel(II) oxide, 2+ (b) manganese(IV) oxide, 4+ (c) chromium(III) oxide, 3+ (d) molybdenium(VI) oxide, 6+ **2.107** (a) Perbromate ion (b) selenite ion (c) AsO_4^{3-} (d) $HTeO_4^-$ **2.110** (a) Potassium nitrate (b) sodium carbonate (c) calcium oxide (d) hydrochloric acid (e) magnesium sulfate (f) magnesium hydroxide

Chapter 3

3.1 Equation (a) best fits the diagram. **3.3** (a) NO_2 (b) No, because we have no way of knowing whether the empirical and molecular formulas are the same. NO_2 represents the simplest ratio of atoms in a molecule but not the only possible molecular formula. **3.5** (a) $C_2H_5NO_2$ (b) 75.0 g/mol (c) 225 g glycine . (d) Mass %N in glycine is 18.7%. **3.7**



$N_2 + 3\ H_2 \longrightarrow 2\ NH_3$. Eight N atoms (4 N_2 molecules) require 24 H atoms (12 H_2 molecules) for complete reaction. Only 9 H_2 molecules are available, so H_2 is the limiting reactant. Nine H_2 molecules (18 H atoms) determine that 6 NH_3 molecules are produced. One N_2 molecule is in excess. **3.9** (a) Conservation of mass (b) Subscripts in chemical formulas should not be changed when balancing equations, because changing the subscript changes the identity of the compound (*law of constant composition*). (c) $H_2O(l)$, $H_2O(g)$, $NaCl(aq)$, $NaCl(s)$ **3.11** (a) $2\ CO(g) + O_2(g) \longrightarrow 2\ CO_2(g)$
(b) $N_2O_5(g) + H_2O(l) \longrightarrow 2\ HNO_3(aq)$
(c) $CH_4(g) + 4\ Cl_2(g) \longrightarrow CCl_4(l) + 4\ HCl(g)$
(d) $Zn(OH)_2(s) + 2HNO_3(aq) \longrightarrow Zn(NO_3)_2(aq) + 2H_2O(l)$
3.13 (a) $A1_4C_3(s) + 12\ H_2O(l) \longrightarrow 4A1(OH)_3(s) + 3CH_4(g)$
(b) $2\ C_5H_{10}O_2(l) + 13\ O_2(g) \longrightarrow 10\ CO_2(g) + 10\ H_2O(g)$
(c) $2\ Fe(OH)_3(s) + 3\ H_2SO_4(aq) \longrightarrow Fe_2(SO_4)_3(aq) + 6\ H_2O(l)$
(d) $Mg_3N_2(s) + 4H_2SO_4(aq) \longrightarrow 3MgSO_4(aq) + (NH_4)_2SO_4(aq)$
3.15 (a) $CaC_2(s) + 2\ H_2O(l) \longrightarrow Ca(OH)_2(aq) + C_2H_2(g)$
(b) $2\ KClO_3(s) \xrightarrow{\Delta} 2\ KCl(s) + 3\ O_2(g)$
(c) $Zn(s) + H_2SO_4(aq) \longrightarrow ZnSO_4(aq) + H_2(g)$
(d) $PCl_3(l) + 3\ H_2O(l) \longrightarrow H_3PO_3(aq) + 3\ HCl(aq)$
(e) $3\ H_2S(g) + 2\ Fe(OH)_3(s) \longrightarrow Fe_2S_3(s) + 6\ H_2O(g)$
3.17 (a) NaBr (b) solid (c) 2 **3.19** (a) $Mg(s) + Cl_2(g) \longrightarrow MgCl_2(s)$
(b) $BaCO_3(s) \xrightarrow{\Delta} BaO(s) + CO_2(g)$
(c) $C_8H_8(l) + 10\ O_2(g) \longrightarrow 8\ CO_2(g) + 4\ H_2O(l)$
(d) $C_2H_6O(g) + 3\ O_2(g) \longrightarrow 2\ CO_2(g) + 3\ H_2O(l)$
3.21 (a) $2\ C_3H_6(g) + 9\ O_2(g) \longrightarrow 6\ CO_2(g) + 6\ H_2O(g)$
combustion
(b) $NH_4NO_3(s) \longrightarrow N_2O(g) + 2\ H_2O(g)$ decomposition
(c) $C_5H_6O(l) + 6\ O_2(g) \longrightarrow 5\ CO_2(g) + 3\ H_2O(g)$ combustion
(d) $N_2(g) + 3\ H_2(g) \longrightarrow 2\ NH_3(g)$ combination
(e) $K_2O(s) + H_2O(l) \longrightarrow 2\ KOH(aq)$ combination

Chapter 4

4.1 Diagram (c) represents Li_2SO_4 **4.5** $BaCl_2$ **4.7** (b) NO_3^- and (c) NH_4^+ will always be spectator ions. **4.13** (a) False. Electrolyte solutions conduct electricity because *ions* are moving through the solution. (b) True. Because ions are mobile in solution, the added presence of uncharged molecules does not inhibit conductivity. **4.15** Statement (b) is most correct. **4.17** (a) $FeCl_2(aq) \longrightarrow Fe^{2+}(aq) + 2\ Cl^-(aq)$
(b) $HNO_3(aq) \longrightarrow H^+(aq) + NO_3^-(aq)$
(c) $(NH_4)_2SO_4(aq) \longrightarrow 2\ NH_4^+(aq) + SO_4^{2-}(aq)$
(d) $Ca(OH_4)_2(aq) \longrightarrow Ca^{2+}(aq) + 2\ OH^-(aq)$
4.19 HCOOH molecules, H^+ ions, and $HCOO^-$ ions;
$HCOOH(aq) \rightleftharpoons H^+(aq) + HCOO^-(aq)$ **4.21** (a) Soluble (b) insoluble (c) soluble (d) soluble (e) soluble **4.23** (a) $Na_2CO_3(aq) + 2\ AgNO_3(aq) \longrightarrow Ag_2CO_3(s) + 2\ NaNO_3(aq)$ (b) No precipitate (c) $FeSO_4(aq) + Pb(NO_3)_2(aq) \longrightarrow PbSO_4(s) + Fe(NO_3)_2(aq)$ **4.25** (a) K^+, SO_4^{2-} (b) Li^+, NO_3^- (c) NH_4^+, Cl^-
4.27 Only Pb^{2+} could be present. **4.29** (a) True (b) false (c) false (d) true (e) false **4.31** The 0.20 *M* HI(*aq*) is most acidic.
4.33 (a) False. H_2SO_4 is a diprotic acid; it has two ionizable hydrogen atoms. (b) False. HCl is a strong acid. (c) False. CH_3OH is a molecular nonelectrolyte. **4.35** (a) Acid, mixture of ions and molecules (weak electrolyte) (b) none of the above, entirely molecules (nonelectrolyte) (c) salt, entirely ions (strong electrolyte) (d) base, entirely ions (strong electrolyte) **4.37** (a) H_2SO_3, weak electrolyte (b) C_2H_5OH,

nonelectrolyte (c) NH_3, weak electrolyte (d) $KClO_3$, strong electrolyte (e) $Cu(NO_3)_2$, strong electrolyte
4.39 (a) $2\ HBr(aq) + Ca(OH)_2(aq) \longrightarrow CaBr(aq) + 2\ H_2O(l)$;
$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$;
(b) $Cu(OH)_2(s) + 2\ HClO_4(aq) \longrightarrow Cu(ClO_4)_2(aq) + 2\ H_2O(l)$;
$Cu(OH)_2(s) + 2\ H^+(aq) \longrightarrow 2\ H_2O(l) + Cu^{2+}(aq)$
(c) $Al(OH)_3(s) + 3\ HNO_3(aq) \longrightarrow Al(NO_3)_3(aq) + 3\ H_2O(l)$;
$Al(OH)_3(s) + 3\ H^+(aq) \longrightarrow 3\ H_2O(l) + Al^{3+}(aq)$
4.41 (a) $CdS(s) + H_2SO_4(aq) \longrightarrow CdSO_4(aq) + H_2S(g)$;
$CdS(s) + 2H^+(aq) \longrightarrow H_2S(g) + Cd^{2+}(aq)$
(b) $MgCO_3(s) + 2\ HClO_4(aq) \longrightarrow Mg(ClO_4)_2(aq) + H_2O(l) + CO_2(g)$;
$MgCO_3(s) + 2\ H^+(aq) \longrightarrow H_2O(l) + CO_2(g) + Mg^{2+}(aq)$
4.43 (a)
$MgCO_3(s) + 2\ HCl(aq) \longrightarrow MgCl_2(aq) + H_2O(l) + CO_2(g)$;
$MgCO_3(s) + 2\ H^+(aq) \longrightarrow Mg^{2+}(aq) + H_2O(l) + CO_2(g)$;
$MgO(s) + 2\ HCl(aq) \longrightarrow MgCl_2(aq) + H_2O(l)$;
$MgO(s) + 2\ H^+(aq) \longrightarrow Mg^{2+}(aq) + H_2O(l)$;
$Mg(OH)_2(s) + 2\ H^+(aq) \longrightarrow Mg^{2+}(aq) + 2\ H_2O(l)$
(b) We can distinguish magnesium carbonate, $MgCO_3(s)$, because its reaction with acid produces $CO_2(g)$, which appears as bubbles. The other two compounds are indistinguishable, because the products of the two reactions are exactly the same. **4.45** (a) False (b) true **4.47** Metals in region A are most easily oxidized. Nonmetals in region D are least easily oxidized. **4.49** (a) +4 (b) +4 (c) +7 (d) +1 (e) +3 (f) −1 **4.51** (a) $N_2 \longrightarrow 2\ NH_3$, N is reduced; $3\ H_2 \longrightarrow 2\ NH_3$, H is oxidized (b) $Fe^{2+} \longrightarrow Fe$, Fe is reduced; $Al \longrightarrow Al^{3+}$, Al is oxidized (c) $Cl_2 \longrightarrow 2\ Cl^-$, Cl is reduced; $2\ I^- \longrightarrow I_2$, I is oxidized (d) $S^{2-} \longrightarrow SO_4^{\ 2-}$, S is oxidized; $H_2O_2 \longrightarrow H_2O$, O is reduced **4.53** (a) $Mn(s) + H_2SO_4(aq) \longrightarrow MnSO_4(aq) + H_2(g)$;
$Mn(s) + 2\ H^+(aq) \longrightarrow Mn^{2+}(aq) + H_2(g)$
(b) $2\ Cr(s) + 6\ HBr(aq) \longrightarrow 2\ CrBr_3(aq) + 3\ H_2(g)$;
$2\ Cr(s) + 6\ H^+(aq) \longrightarrow 2\ Cr^{3+}(aq) + 3\ H_2(g)$
(c) $Sn(s) + 2\ HCl(aq) \longrightarrow SnCl_2(aq) + H_2(g)$;
$Sn(s) + 2\ H^+(aq) \longrightarrow Sn^{2+}(aq) + H_2(g)$
(d) $2\ Al(s) + 6\ HCOOH(aq) \longrightarrow 2\ Al(HCOO)_3(aq) + 3\ H_2(g)$;
$2\ Al(s) + 6\ HCOOH(aq) \longrightarrow 2\ Al^{3+}(aq) + 6\ HCOO^-(aq) + 3\ H_2(g)$
4.55 (a) $Fe(s) + Cu(NO_3)_2(aq) \longrightarrow Fe(NO_3)_2(aq) + Cu(s)$
(b) NR (c) $Sn(s) + 2\ HBr(aq) \longrightarrow SnBr_2(aq) + H_2(g)$
(d) NR (e) $2\ Al(s) + 3\ CoSO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + 3\ Co(s)$
4.57 (a) i. $Zn(s) + Cd^{2+}(aq) \longrightarrow Cd(s) + Zn^{2+}(aq)$;
ii. $Cd(s) + Ni^{2+}(aq) \longrightarrow Ni(s) + Cd^{2+}(aq)$ (b) The elements chromium, iron and cobalt more closely define the position of cadmium in the activity series. (c) Place an iron strip in $CdCl_2(aq)$. If $Cd(s)$ is deposited, Cd is less active than Fe; if there is no reaction, Cd is more active than Fe. Do the same test with Co if Cd is less active than Fe or with Cr if Cd is more active than Fe. **4.59** (a) Intensive; the ratio of amount of solute to total amount of solution is the same, regardless of how much solution is present. (b) The term 0.50 mol-HCl defines an amount (~18 g) of the pure substance HCl. The term 0.50 *M* HCl is a ratio; it indicates that there is 0.50 mol of HCl solute in 1.0 liter of solution. **4.61** (a) 1.17 *M* $ZnCl_2$ (b) 0.158 mol H^+ (c) 58.3 mL of 6.00 *M* NaOH **4.63** 16 g $Na^+(aq)$ **4.65** BAC of 0.08 = 0.02 *M* CH_3CH_2OH (alcohol) **4.67** (a) 316 g ethanol (b) 401 mL ethanol **4.69** (a) 0.15 *M* K_2CrO_4 has the highest K^+ concentration. (c) 2.62 *M* HNO_3 **4.109** (a) $Mg(OH)_2(s) + 2\ HNO_3(aq) \longrightarrow Mg(NO_3)_2(aq) + 2\ H_2O(l)$ (b) HNO_3 is the limiting reactant.
(c) 0.130 mol $Mg(OH)_2$, 0 mol HNO_3, and 0.00250 mol $Mg(NO_3)_2$ are present. **4.113** (a) +5 (b) silver arsenate (c) 5.22 % As

Chapter 5

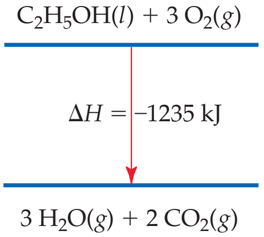
5.1 (a) As the book falls, potential energy decreases and kinetic energy increases. (b) The initial potential energy of the book and its total kinetic energy at the instant before impact are both 71 J, assuming no transfer of energy as heat. (c) A heavier book falling from the same shelf has greater kinetic energy when it hits the floor. **5.4** (a) (iii) (b) none of them (c) all of them **5.7** (a) The sign of w is (+). (b) The sign of q is (−). (c) The sign of w is positive and the sign of q is negative, so we cannot absolutely determine the sign of ΔE. It is likely that the heat lost is much smaller than the work done on the system, so the sign of ΔE is probably positive. **5.10** (a) $N_2(g) + O_2(g) \longrightarrow 2NO(g)$. Since $\Delta V = 0$, $w = 0$. (b) $\Delta H = \Delta H_f = 90.37$ kJ. The definition of a formation reaction is one where elements combine to form one mole of a single product. The enthalpy change for such a reaction is the enthalpy of formation. **5.13** An object can possess energy by virtue of its motion or position. Kinetic energy depends on the mass of the object and its velocity. Potential energy depends on the position of the object relative to the body with which it interacts. **5.15** (a) 1.9×10^5 J (b) 4.6×10^4 cal (c) As the automobile brakes to a stop, its speed (and hence its kinetic energy) drops to zero. The kinetic energy of the automobile is primarily transferred to friction between brakes and wheels and somewhat to deformation of the tire and friction between the tire and road. **5.17** 1 Btu = 1054 J **5.19** (a) The *system* is the well-defined part of the universe whose energy changes are being studied. (b) A *closed system* can exchange heat but not mass with its surroundings. (c) Any part of the universe not part of the system is called the surroundings. **5.21** (a) Gravity; work is done because the force of gravity is opposed and the pencil is lifted. (b) Mechanical force; work is done because the force of the coiled spring is opposed as the spring is compressed over a distance. **5.23** (a) In any chemical or physical change, energy can be neither created nor destroyed; energy is conserved. (b) The *internal energy (E)* of a system is the sum of all the kinetic and potential energies of the system components. (c) Internal energy of a closed system increases when work is done on the system and when heat is transferred to the system. **5.25** (a) $\Delta E = -0.077$ kJ, endothermic (b) $\Delta E = -22.1$ kJ, exothermic **5.27** (a) Since no work is done by the system in case (2), the gas will absorb most of the energy as heat; the case (2) gas will have the higher temperature. (b) In case (2) $w = 0$ and $q = 100$ J. In case (1) energy will be used to do work on the surroundings ($-w$), but some will be absorbed as heat ($+q$). (c) ΔE is greater for case (2) because the entire 100 J increases the internal energy of the system rather than a part of the energy doing work on the surroundings. **5.29** (a) A *state function* is a property that depends only on the physical state (pressure, temperature, etc.) of the system, not on the route used to get to the current state. (b) Internal energy is a state function; heat is not a state function. (c) Volume is a state function. The volume of a system depends only on conditions (pressure, temperature, amount of substance), not the route or method used to establish that volume. **5.31** −51 J **5.33** (a) ΔH is usually easier to measure than ΔE because at constant pressure, $\Delta H = q_p$. The heat flow associated with a process at constant pressure can easily be measured as a change in temperature, while measuring ΔE requires a means to measure both q and w. (b) H is a static quantity that depends only on the specific conditions of the system. q is an energy *change* that, in the general case, does depend on how the change occurs. We can equate change in enthalpy, ΔH, with heat, q_p, only for the specific conditions of constant pressure and exclusively P-V work. (c) The process is endothermic. **5.35** (a) We must know either the temperature, T, or the values of P and ΔV in order to calculate ΔE from ΔH. (b) ΔE is larger than ΔH. (c) Since the value of Δn is negative, the quantity $(-P\Delta V)$ is positive. We add a positive quantity to ΔH to calculate ΔE, so ΔE must be larger.

5.37 $\Delta E =\ 1.47$ kJ; $\Delta H = 0.824$ kJ

5.39 (a)

$C_2H_5OH(l) + 3\,O_2(g) \longrightarrow 3\,H_2O + 2\,CO_2(g),\ \Delta H = -1235$ kJ

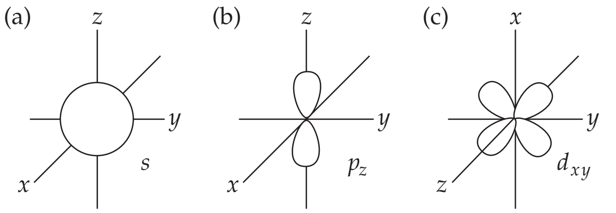
(b)



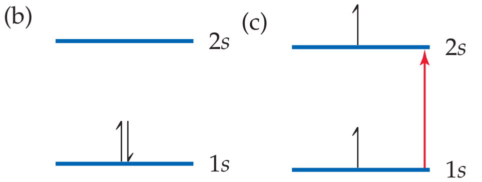
5.41 (a) $\Delta H = -142.3$ kJ/mol $O_3(g)$ (b) $2\,O_3(g)$ has the higher enthalpy. **5.43** (a) Exothermic (b) −87.9 kJ heat transferred (c) 15.7 g MgO produced (d) 602 kJ heat absorbed **5.45** (a) −29.5 kJ (b) −4.11 kJ (c) 60.6 J **5.47** (a) $\Delta H = 726.5$ kJ (b) $\Delta H = -1453$ kJ (c) The exothermic forward reaction is more likely to be thermodynamically favored. (d) Vaporization is endothermic. If the product were $H_2O(g)$, the reaction would be more endothermic and would have a less negative ΔH. **5.49** (a) J/mol-°C or J/mol-K (b) J/g-°C or J/g-K (c) To calculate heat capacity from specific heat, the mass of the particular piece of copper pipe must be known. **5.51** (a) 4.184 J/g-K (b) 75.40 J/mol-°C (c) 774 J/°C (d) 904 kJ **5.53** (a) 2.66×10^3 J (b) It will require more heat to increase the temperature of one mole of octane, $C_8H_{18}(l)$, by a certain amount than to increase the temperature of one mole of water, $H_2O(l)$, by the same amount. **5.55** $\Delta H = -44.4$ kJ/mol NaOH **5.57** $\Delta H_{rxn} = -25.5$ kJ/g $C_6H_4O_2$ or -2.75×10^3 kJ/mol $C_6H_4O_2$ **5.59** (a) Heat capacity of the complete calorimeter = 14.4 kJ/°C (b) 7.56 °C **5.61** Hess's law is a consequence of the fact that enthalpy is a state function. Since ΔH is independent of path, we can describe a process by any series of steps that adds up to the overall process. ΔH for the process is the sum of ΔH values for the steps. **5.63** $\Delta H = -1300.0$ kJ **5.65** $\Delta H = -2.49 \times 10^3$ kJ **5.67** (a) *Standard conditions* for enthalpy changes are $P =$ 1 atm and some common temperature, usually 298 K. (b) *Enthalpy of formation* is the enthalpy change that occurs when a compound is formed from its component elements. (c) *Standard enthalpy of formation*, ΔH_f°, is the enthalpy change that accompanies formation of one mole of a substance from elements in their standard states. **5.69** (a) $\frac{1}{2}N_2(g) + O_2(g) \longrightarrow NO_2(g),\ \Delta H_f^\circ = 33.84$ kJ (b) $S(s) + \frac{3}{2}O_2(g) \longrightarrow SO_3(g),\ \Delta H_f^\circ = -395.2$ kJ (c) $Na(s) + \frac{1}{2}Br_2(l) \longrightarrow NaBr(s),\ \Delta H_f^\circ = -361.4$ kJ (d) $Pb(s) + N_2(g) + 3\,O_2(g) \longrightarrow Pb(NO_3)_2(s), \Delta H_f^\circ = -451.9$ kJ **5.71** $\Delta H_{rxn}^\circ = -847.6$ kJ **5.73** (a) $\Delta H_{rxn}^\circ = -196.6$ kJ (b) $\Delta H_{rxn}^\circ = 37.1$ kJ (c) $\Delta H_{rxn}^\circ = -976.94$ kJ (d) $\Delta H_{rxn}^\circ = -68.3$ kJ **5.75** $\Delta H_f^\circ = -248$ kJ **5.77** (a) $C_8H_{18}(l) + \frac{25}{2}O_2(g) \longrightarrow 8\,CO_2(g) + 9\,H_2O(g)$ (b) $\Delta H_f^\circ = -259.5$ kJ **5.79** (a) $C_2H_5OH(l) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 3\,H_2O(g)$ (b) $\Delta H_{rxn}^\circ = -1234.8$ kJ (c) 2.11×10^4 kJ/L heat produced (d) 0.071284 g CO_2/kJ heat emitted **5.81** (a) *Fuel value* is the amount of energy produced when 1 g of a substance (fuel) is combusted. (b) 5 g of fat (c) These products of metabolism are expelled as waste via the alimentary tract, $H_2O(l)$ primarily in urine and feces, and $CO_2(g)$ as gas when breathing. **5.83** (a) 108 or 1×10^2 Cal/serving (b) Sodium does not contribute to the calorie content of the food because it is not metabolized by the body. **5.85** 59.7 Cal **5.87** (a) $\Delta H_{comb} = -1850$ kJ/mol C_3H_4, −1926 kJ/mol C_3H_6, −2044 kJ/mol C_3H_8 (b) $\Delta H_{comb} = -4.616 \times 10^4$ kJ/kg C_3H_4, -4.578×10^4 kJ/kg C_3H_6, -4.635×10^4 kJ/kg C_3H_8 (c) These three substances yield nearly identical quantities of heat per unit mass, but propane is marginally higher than the other two. **5.89** 1.0×10^{12} kg $C_6H_{12}O_6$/yr **5.91** (a) 469.4 m/s (b) 5.124×10^{-21} J (c) 3.086 kJ/mol **5.93** The spontaneous air bag reaction is probably exothermic, with $-\Delta H$ and thus $-q$. When the bag inflates, work is done by the system, so the sign of w is also negative. **5.97** $\Delta H = 38.95$ kJ; $\Delta E = 36.48$ kJ **5.99** 1.8×10^4 bricks **5.102** (a) $\Delta H_{rxn}^\circ = -353.0$ kJ (b) 1.2 g Mg needed **5.106** (a) $\Delta H^\circ = -631.3$ kJ (b) 3 mol of acetylene gas has greater enthalpy. (c) Fuel values are 50 kJ/g $C_2H_2(g)$, 42 kJ/g $C_6H_6(l)$. **5.109** If all work is used to increase the man's potential energy, the stair climbing uses 58 Cal and will not compensate for the extra order of 245 Cal fries. (More than 58 Cal will be required to climb the stairs because some energy is used to move limbs and some will be lost as heat.) **5.112** (a) 1.479×10^{-18} J/molecule (b) 1×10^{-15} J/photon. The X-ray has approximately 1000 times more energy than is produced by the combustion of 1 molecule of $CH_4(g)$. **5.114** (a) ΔH° for neutralization of the acids is HNO_3, −55.8 kJ; HCl, −56.1 kJ; NH_4^+, −4.1 kJ. (b) $H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$ is the net ionic equation for the first two reactions. $NH_4^+(aq) + OH^-(aq) \longrightarrow NH_3(aq) + H_2O(l)$ (c) The ΔH° values for the first two reactions are nearly identical, −55.8 kJ and −56.1 kJ. Since spectator ions do not change during a reaction and these two reactions have the same net ionic equation, it is not surprising that they have the same ΔH°. (d) Strong acids are more likely than weak acids to donate H^+. Neutralization of the two strong acids is energetically favorable, while the third reaction is barely so. NH_4^+ is likely a weak acid. **5.116** (a) $\Delta H^\circ = -65.7$ kJ (b) ΔH° for the complete molecular equation will be the same as ΔH° for the net ionic equation. Since the overall enthalpy change is the enthalpy of products minus the enthalpy of reactants, the contributions of spectator ions cancel. (c) ΔH_f° for $AgNO_3(aq)$ is −100.4 kJ/mol.

Chapter 6

6.2 (a) 0.1 m or 10 cm (b) No. Visible radiation has wavelengths much shorter than 0.1 m. (c) Energy and wavelength are inversely proportional. Photons of the longer 0.1-m radiation have less energy than visible photons. (d) Radiation with $\lambda = 0.1$ m is in the low-energy portion of the microwave region. The appliance is probably a microwave oven. **6.6** (a) Increase (b) Decrease (c) The light from the hydrogen discharge tube is a line spectrum, so not all visible wavelengths will be in our "hydrogen discharge rainbow." Starting on the inside, the rainbow will be violet, then blue and blue-green. After a gap, the final band will be red. **6.9** (a) 1 (b) p (c) (ii) **6.13** (a) Meters (b) 1/second (c) meters/second **6.15** (a) True (b) False. Ultraviolet light has shorter wavelengths than visible light. (c) False. X-rays travel at the same speed as microwaves. (d) False. Electromagnetic radiation and sound waves travel at different speeds. **6.17** Wavelength of X-rays < ultraviolet < green light < red light < infrared < radio waves **6.19** (a) 3.0×10^{13} s^{-1} (b) 5.45×10^{-7} m = 545 nm. (c) The radiation in (b) is visible; the radiation in (a) is not. (d) 1.50×10^4 m **6.21** 4.61×10^{14} s^{-1}; red. **6.23** (iii) **6.25** (a) 1.95×10^{-19} J (b) 4.81×10^{-19} J (c) 328 nm **6.27** (a) $\lambda = 3.3\ \mu$m, $E = 6.0 \times 10^{-20}$ J; $\lambda = 0.154$ nm, $E = 1.29 \times 10^{-15}$ J (b) The 3.3-μm photon is in the infrared region and the 0.154-nm photon is in the X-ray region; the X-ray photon has the greater energy. **6.29** (a) 6.11×10^{-19} J/photon (b) 368 kJ/mol (c) 1.64×10^{15} photons (d) 368 kJ/mol **6.31** (a) The $\sim 1 \times 10^{-6}$ m radiation is in the infrared portion of the spectrum. (b) 8.1×10^{16} photons/s **6.33** (a) $E_{min} = 7.22 \times 10^{-19}$ J (b) $\lambda = 275$ nm (c) $E_{120} = 1.66 \times 10^{-18}$ J. The excess energy of the 120-nm photon is converted into the kinetic energy of the emitted electron. $E_k = 9.3 \times 10^{-19}$ J/electron. **6.35** When applied to atoms, the notion of quantized energies means that only certain values of ΔE are allowed. These are represented by the lines in the emission spectra of excited atoms. **6.37** (a) Emitted (b) absorbed (c) emitted **6.39** (a) $E_2 = -5.45 \times 10^{-19}$ J; $E_6 = -0.606 \times 10^{-19}$ J; $\Delta E = 4.84 \times 10^{-19}$ J; $\lambda = 410$ nm (b) visible, violet **6.41** (a) (ii) (b) $n_i = 3$, $n_f = 2$; $\lambda = 6.56 \times 10^{-7}$ m; this is the red line at 656 nm. $n_i = 4$, $n_f = 2$; $\lambda = 4.86 \times 10^{-7}$ m; this is the blue-green line at 486 nm. $n_i = 5$, $n_f = 2$; $\lambda = 4.34 \times 10^{-7}$ m; this is the blue-violet line at 434 nm. **6.43** (a) Ultraviolet region (b) $n_i = 7$, $n_f = 1$ **6.45** The order of increasing frequency of light absorbed is: $n = 4$ to $n = 9$; $n = 3$ to $n = 6$; $n = 2$ to $n = 3$; $n = 1$ to $n = 2$ **6.47** (a) $\lambda = 5.6 \times 10^{-37}$ m (b) $\lambda = 2.65 \times 10^{-34}$ m (c) $\lambda = 2.3 \times 10^{-13}$ m (d) $\lambda = 1.51 \times 10^{-11}$ m **6.49** 3.16×10^3 m/s **6.51** (a) $\Delta x \geq 4 \times 10^{-27}$ m (b) $\Delta x \geq 3 \times 10^{-10}$ m **6.53** (a) The uncertainty principle states that there is a limit to how precisely we can simultaneously know the position and momentum (a quantity related to energy) of an electron. The Bohr model states that electrons move about the nucleus in precisely circular orbits of known radius and energy. This violates the uncertainty principle. (b) De Broglie stated that electrons demonstrate the properties of both particles and waves and that each moving particle has a wave associated with it. A wave function is the mathematical description of the matter wave of an electron. (c) Although we cannot predict the exact location of an electron in an allowed energy state, we can determine the probability of finding an electron at a particular position. This statistical knowledge of electron location is the *probability density* and is a function of ψ^2, the square of the wave function ψ. **6.55** (a) $n = 4$, $l = 3, 2, 1, 0$ (b) $l = 2$, $m_l = -2, -1, 0, 1, 2$ (c) $m_l = 2$, $l \geq 2$ or $l = 2, 3$ or 4 **6.57** (a) $3p$: $n = 3$, $l = 1$ (b) $2s$: $n = 2$, $l = 0$ (c) $4f$: $n = 4$, $l = 3$ (d) $5d$: $n = 5$, $l = 2$ **6.59** (a) 2, 1, 0, −1, −2 (b) $\frac{1}{2}$, $-\frac{1}{2}$ **6.61** (a) impossible, $1p$ (b) possible (c) possible (d) impossible, $2d$ **6.63**



6.65 (a) The hydrogen atom $1s$ and $2s$ orbitals have the same overall spherical shape, but the $2s$ orbital has a larger radial extension and one more node than the $1s$ orbital. (b) A single $2p$ orbital is directional in that its electron density is concentrated along one of the three Cartesian axes of the atom. The $d_{x^2-y^2}$ orbital has electron density along both the x- and y-axes, while the p_x orbital has density only along the x-axis. (c) The average distance of an electron from the nucleus in a $3s$ orbital is greater than for an electron in a $2s$ orbital. (d) $1s < 2p < 3d < 4f < 6s$ **6.67** (a) In the hydrogen atom, orbitals with the same principal quantum number, n, have the same energy. (b) In a many-electron atom, for a given n value, orbital energy increases with increasing l value: $s < p < d < f$. **6.69** (a)There are two main pieces of experimental evidence for electron "spin." The Stern-Gerlach experiment shows that atoms with a single unpaired electron interact differently with an inhomogeneous magnetic field. Examination of the fine details of emission line spectra of multi-electron atoms reveals that each line is really a close pair of lines. Both observations can be rationalized if electrons have the property of spin.



6.71 (a) 6 (b) 10 (c) 2 (d) 14 **6.73** (a) "Valence electrons" are those involved in chemical bonding. They are part or all of the outer-shell electrons listed after the core. (b) "Core electrons" are inner-shell electrons that have the electron configuration of the nearest noble-gas element. (c) Each box represents an orbital. (d) Each half-arrow in an orbital diagram represents an electron. The direction of the half-arrow represents electron spin. **6.75** (a) Cs, $[\mathrm{Xe}]6s^1$ (b) Ni, $[\mathrm{Ar}]4s^23d^8$ (c) Se, $[\mathrm{Ar}]4s^23d^{10}4p^4$ (d) Cd, $[\mathrm{Kr}]5s^24d^{10}$ (e) U, $[\mathrm{Rn}]5f^36d^17s^2$ (f) Pb, $[\mathrm{Xe}]6s^24f^{14}5d^{10}6p^2$ **6.77** (a) Be, 0 unpaired electrons (b) O, 2 unpaired electrons (c) Cr, 6 unpaired electrons (d) Te, 2 unpaired electrons **6.79** (a) The fifth electron would fill the $2p$ subshell before the $3s$. (b) Either the core is [He], or the outer electron configuration should be $3s^23p^3$. (c) The $3p$ subshell would fill before the $3d$. **6.81** (a) $\lambda_A = 3.6 \times 10^{-8}$ m,$\lambda_B = 8.0 \times 10^{-8}$ m (b) $\nu_A = 8.4 \times 10^{15}\ \mathrm{s}^{-1}$, $\nu_B = 3.7 \times 10^{15}\ \mathrm{s}^{-1}$ (c) A, ultraviolet; B, ultraviolet **6.84** (a) 8.93×10^3 mi/hr (b) 35.0 min **6.86** 1.6×10^{18} photons **6.91** (a) The Paschen series lies in the infrared. (b) $n_i = 4$, $\lambda = 1.87 \times 10^{-6}$ m; $n_i = 5$, $\lambda = 1.28 \times 10^{-6}$ m; $n_i = 6$, $\lambda = 1.09 \times 10^{-6}$ m **6.95** $\lambda = 10.6$ pm **6.99** (a) The nodal plane of the p_z orbital is the xy-plane. (b) The two nodal planes of the d_{xy} orbital are the ones where $x = 0$ and $y = 0$. These are the yz- and xz-planes. (c) The two nodal planes of the $d_{x^2-y^2}$ orbital are the ones that bisect the x- and y-axes and contain the z-axis. **6.102** (a) Br: $[\mathrm{Ar}]4s^23d^{10}4p^5$, 1 unpaired electron (b) Ga: $[\mathrm{Ar}]4s^23d^{10}4p^1$, 1 unpaired electron (c) Hf: $[\mathrm{Xe}]6s^24f^{14}5^2$, 2 unpaired electrons (d) Sb: $[\mathrm{Kr}]5s^24d^{10}5p^3$, 3 unpaired electrons (e) Bi: $[\mathrm{Xe}]6s^24f^{14}5d^{10}6p^3$, 3 unpaired electrons (f) Sg: $[\mathrm{Rn}]7s^25f^{14}6d^4$, 4 unpaired electrons **6.105** (a) 1.7×10^{28} photons (b) 34 s **6.109** (a) Bohr's theory was based on the Rutherford nuclear model of the atom: a dense positive charge at the center and a diffuse negative charge surrounding it. Bohr's theory then specified the nature of the diffuse negative charge. The prevailing theory before the nuclear model was Thomson's plum pudding model: discrete electrons scattered about a diffuse positive charge cloud. Bohr's theory could not have been based on the Thomson model of the atom. (b) De Broglie's hypothesis is that electrons exhibit both particle and wave properties. Thomson's conclusion that electrons have mass is a particle property, while the nature of cathode rays is a wave property. De Broglie's hypothesis actually rationalizes these two seemingly contradictory observations about the properties of electrons.

Chapter 7

7.2 The largest brown sphere is Br^-, the intermediate blue one is Br, and the smallest red one is F. **7.5** (a) The bonding atomic radius of A, r_A, is $d_1/2$; $r_x = d_2 - (d_1/2)$. (b) The length of the X—X bond is $2r_x$ or $2d_2 - d_1$. **7.8** (a) $\mathrm{X} + 2\mathrm{F}_2 \longrightarrow \mathrm{XF}_4$ (b) X in the diagram has about the same bonding radius as F, so it is likely to be a nonmetal. **7.9** (a) The results are 2, 8, 18, 32. (b) The atomic numbers of the noble gases are 2, 10, 18, 36, 54 and 86. The differences between sequential pairs of these atomic numbers is 8, 8, 18, 18 and 32. These differences correspond to the results in (a). They represent the filling of new subshells when moving across the next row of the periodic chart. (c) The Pauli exclusion principle is the source of the "2". **7.11** In general, elements are discovered according to their ease of isolation in elemental form. **7.13** (a) *Effective nuclear charge*, Z_{eff}, is a representation of the average electrical field experienced by a single electron. It is the average environment created by the nucleus and the other electrons in the molecule, expressed as a net positive charge at the nucleus. (b) Going from left to right across a period, effective nuclear charge increases. **7.15** (a) For both Na and K, $Z_{\mathrm{eff}} = 1$. (b) For both Na and K, $Z_{\mathrm{eff}} = 2.2$. (c) Slater's rules give values closer to the detailed calculations: Na, 2.51; K, 3.49. (d) Both approximations give the same value of Z_{eff} for Na and K; neither accounts for the gradual increase in Z_{eff} moving down a group. (e) Following the trend from detailed calculations, we predict a Z_{eff} value of approximately 4.5. **7.17** The $n = 3$ electrons in Kr experience a greater effective nuclear charge and thus have a greater probability of being closer to the nucleus. **7.19** (a) Atomic radii are determined by measuring distances between atoms in various situations. (b) Bonding radii are calculated from the internuclear separation of two atoms joined by a covalent chemical bond. Nonbonding radii are calculated from the internuclear separation between two gaseous atoms that collide and move apart but do not bond. (c) For a given element, the nonbonding radius is always larger than the bonding radius. (d) If a free atom reacts to become part of a covalent molecule, its radius changes from nonbonding to bonding and the atom gets smaller. **7.21** (a) 1.37 Å (b) The distance between W atoms will decrease. **7.23** From the sum of the atomic radii, As—I = 2.58 Å. This is very close to the experimental value of 2.55 Å. **7.25** (a) Cs > K > Li (b) Pb > Sn > Si (c) N > O > F **7.27** (a) False (b) true (c) false **7.29** Ga^{3+}: none; Zr^{4+}: Kr; Mn^{7+}: Ar; I^-: Xe; Pb^{2+}: Hg **7.31** (a) Na^+ (b) F^-, $Z_{eff} = 7$; Na^+, $Z_{eff} = 9$ (c) $S = 4.15$; F^-, $Z_{eff} = 4.85$; Na^+, $Z_{eff} = 6.85$ (d) For isoelectronic ions, as nuclear charge (Z) increases, effective nuclear charge (Z_{eff}) increases and ionic radius decreases. **7.33** (a) Cl < S < K (b) $K^+ < Cl^- < S^{2-}$ (c) The neutral K atom has the largest radius because the *n*-value of its outer electron is larger than the *n*-value of valence electrons in S and Cl. The K^+ ion is smallest because, in an isoelectronic series, the ion with the largest Z has the smallest ionic radius. **7.35** (a) O^{2-} is larger than O because the increase in electron repulsions that accompanies addition of an electron causes the electron cloud to expand. (b) S^{2-} is larger than O^{2-} because for particles with like charges, size increases going down a family. (c) S^{2-} is larger than K^+ because the two ions are isoelectronic and K^+ has the larger Z and Z_{eff}. (d) K^+ is larger than Ca^{2+} because the two ions are isoelectronic and Ca^{2+} has the larger Z and Z_{eff}. **7.37** $Al(g) \longrightarrow Al^+(g) + 1e^-$; $Al^+(g) \longrightarrow Al^{2+}(g) + 1e^-$; $Al^{2+}(g) \longrightarrow Al^{3+}(g) + 1e^-$. The process for the first ionization energy requires the least amount of energy. **7.39** (a) The outer electron in Li has a smaller *n*-value and is closer to the nucleus. More energy is needed to overcome the greater attraction of the Li electron for the nucleus. (b) Sc: [Ar] $4s^23d^1$; Ti: [Ar]$4s^23d^2$. The fourth ionization of titanium involves removing a 3*d* valence electron, while the fourth ionization of Sc requires removing a 3*p* electron from the [Ar] core. The core electron has a greater Z_{eff} and requires more energy to remove. (c) Li: $[He]2s^1$; Be: $[He]2s^2$. The second ionization of Be involves removing a 2*s* valence electron, while the second ionization of Li requires removing a 1*s* core electron. The core electron is closer to the nucleus and requires more energy to remove. **7.41** (a) The smaller the atom, the larger its first ionization energy. (b) Of the nonradioactive elements, He has the largest and Cs has the smallest first ionization energy. **7.43** (a) Cl (b) Ca (c) K (d) Ge (e) Sn **7.45** (a) $Co^{2+}, [Ar]3d^7$ (b) $Sn^{2+}, [Kr]5s^24d^{10}$ (c) $Zr^{4+}, [Kr]$, noble gas configuration (d) $Ag^+, [Kr]4d^{10}$ (e) S^{2-}, $[Ne]3s^23p^6$, noble gas configuration **7.47** $Ni^{2+}, [Ar]3d^8$; $Pd^{2+}, [Kr]4d^8$; $Pt^{2+}, [Xe]4f^{14}5d^8$ **7.49** (a) Positive, endothermic, values for ionization energy and electron affinity mean that energy is required to either remove or add electrons. Valence electrons in Ar experience the largest Z_{eff} of any element in the third row, resulting in a large, positive ionization energy. When an electron is added to Ar, the $n = 3$ electrons become core electrons that screen the extra electron so effectively that Ar^- has a higher energy than an Ar atom and a free electron. This results in a large positive electron affinity. (b) kJ/mol **7.51** Electron affinity of Br: $Br(g) + 1e^- \longrightarrow Br^-(g)$; $[Ar]4s^23d^{10}4p^5 \longrightarrow [Ar]4s^23d^{10}4p^6$; electron affinity of Kr: $Kr(g) + 1e^- \longrightarrow Kr^-(g)$; $[Ar]4s^23d^{10}4p^6 \longrightarrow [Ar]4s^23d^{10}4p^65s^1$. Br^- adopts the stable electron configuration of Kr; the added electron experiences essentially the same Z_{eff} and stabilization as the other valence electrons and electron affinity is negative. In Kr^- ion, the added electron occupies the higher energy 5*s* orbital. A 5*s* electron is farther from the nucleus, effectively shielded by the spherical Kr core and not stabilized by the nucleus; electron affinity is positive. **7.53** (a) Ionization energy (I_1) of Ne: $Ne(g) \longrightarrow Ne^+(g) + 1e^-$; $[He]2s^22p^6 \longrightarrow [He]2s^22p^5$; electron affinity ($E_1$) of F: $F(g) + 1e^- \longrightarrow F^-(g)$; $[He]2s^22p^5 \longrightarrow [He]2s^22p^6$. (b) I_1 of Ne is positive; E_1 of F is negative. (c) One process is apparently the reverse of the other, with one important difference. Ne has a greater Z and Z_{eff}, so we expect I_1 for Ne to be somewhat greater in magnitude and opposite in sign to E_1 for F. **7.55** (a) Decrease (b) Increase (c) The smaller the first ionization energy of an element, the greater the metallic character of that element. The trends in (a) and (b) are the opposite of the trends in ionization energy. **7.57** Agree. When forming ions, all metals form cations. The only nonmetallic element that forms cations is the metalloid Sb, which is likely to have significant metallic character. **7.59** Ionic: SnO_2, Al_2O_3, Li_2O, Fe_2O_3; molecular: CO_2, H_2O. Ionic compounds are formed by combining a metal and a nonmetal; molecular compounds are formed by two or more nonmetals. **7.61** (a) An *acidic oxide* dissolved in water produces an acidic solution; a *basic oxide* dissolved in water produces a basic solution. (b) Oxides of nonmetals, such as SO_3, are acidic; oxides of metals, such as CaO, are basic. **7.63** (a) Dichlorine heptoxide (b) $2\,Cl_2(g) + 7\,O_2(g) \longrightarrow 2\,Cl_2O_7(l)$ (c) A boiling point of 81 °C is not unexpected for a large molecule like Cl_2O_7. (d) Cl_2O_7 is an acidic oxide, so it will be more reactive to base, OH^-. (e) The oxidation state of Cl in Cl_2O_7 is +7; the corresponding electron configuration for Cl is $[He]2s^22p^6$ or [Ne]. **7.65** (a) $BaO(s)\ H_2O(l) \longrightarrow Ba(OH)_2(aq)$ (b) $FeO(s) + 2\,HClO_4(aq) \longrightarrow Fe(ClO_4)_2(aq) + H_2O(l)$ (c) $SO_3(g) + H_2O(l) \longrightarrow H_2SO_4(aq)$ (d) $CO_2(g) + 2\,NaOH(aq) \longrightarrow Na_2CO_3(aq) + H_2O(l)$ **7.67** (a) Ca is more reactive because it has a lower ionization energy than Mg. (b) K is more reactive because it has a lower ionization energy than Ca.

7.69 (a) $2\,K(s) + Cl_2(g) \longrightarrow 2\,KCl(s)$
(b) $SrO(s) + H_2O(l) \longrightarrow Sr(OH)_2(aq)$
(c) $4\,Li(s) + O_2(g) \longrightarrow 2\,Li_2O(s)$
(d) $2\,Na(s) + S(l) \longrightarrow Na_2S(s)$ **7.71** (a) Both classes of reaction are redox reactions where either hydrogen or the halogen gains electrons and is reduced. The product is an ionic solid, where either hydride ion, H^-, or a halide ion, X^-, is the anion. (b) $Ca(s) + F_2(g) \longrightarrow CaF_2(s)$; $Ca(s) + H_2(g) \longrightarrow CaH_2(s)$. Both products are ionic solids containing Ca^{2+} and the corresponding anion in a 1:2 ratio. **7.73** (a) Br, $[Ar]4s^24p^5$; Cl, $[Ne]3s^23p^5$ (b) Br and Cl are in the same group, and both adopt a 1− ionic charge. (c) The ionization energy of Br is smaller than that of Cl, because the 4*p* valence electrons in Br are farther from to the nucleus and less tightly held than the 3*p* electrons of Cl. (d) Both react slowly with water to form HX + HOX. (e) The electron affinity of Br is less negative than that of Cl, because the electron added to the 4*p* orbital in Br is farther from the nucleus and less tightly held than the electron added to the 3*p* orbital of Cl. (f) The atomic radius of Br is larger than that of Cl, because the 4*p* valence electrons in Br are farther from the nucleus and less tightly held than the 3*p* electrons of Cl. **7.75** (a) The term *inert* was dropped because it no longer described all the Group 8A elements. (b) In the 1960s, scientists discovered that Xe would react with substances having a strong tendency to remove electrons, such as F_2. Thus, Xe could not be categorized as an "inert" gas. (c) The group is now called the noble gases. **7.77** (a) $2\,O_3(g) \longrightarrow 3\,O_2(g)$ (b) $Xe(g) + F_2(g) \longrightarrow XeF_2(g)$; $Xe(g) + 2\,F_2(g) \longrightarrow XeF_4(s)$; $Xe(g) + 3\,F_2(g) \longrightarrow XeF_6(s)$ (c) $S(s) + H_2(g) \longrightarrow H_2S(g)$
(d) $2\,F_2(g) + 2\,H_2O(l) \longrightarrow 4\,HF(aq) + O_2(g)$

7.79 Up to $Z = 82$, there are three instances where atomic weights are reversed relative to atomic numbers: Ar and K; Co and Ni; Te and I. **7.81** (a) 5+ (b) 4.8+ (c) Shielding is greater for 3*p* electrons, owing to penetration by 3*s* electrons, so Z_{eff} for 3*p* electrons is less than that for 3*s* electrons. (d) The first electron lost is a 3*p* electron because it has a smaller Z_{eff} and experiences less attraction for the nucleus than a 3*s* electron does. **7.85** (a) The As−Cl distance is 2.24 Å. (b) The predicted As−Cl bond length is 2.21 Å **7.87** (a) Chalcogens, −2; halogens, −1. (b) The family with the larger value is: atomic radii, chalcogens; ionic radii of the most common oxidation state, chalcogens; first ionization energy, halogens; second ionization energy, halogens **7.91** $C{:}1s^22s^22p^2$. I_1 through I_4 represent loss of the 2*p* and 2*s* electrons in the outer shell of the atom. The values of $I_1 - I_4$ increase as expected. I_5 and I_6 represent loss of the 1*s* core electrons. These 1*s* electrons are much closer to the nucleus and experience the full nuclear charge, so the values of I_5 and I_6 are significantly greater than $I_1 - I_4$. **7.96** (a) Cl^-, K^+ (b) Mn^{2+}, Fe^{3+} (c) Sn^{2+}, Sb^{3+} **7.99** (a) For both H and the alkali metals, the added electron will complete an *ns* subshell, so shielding and repulsion effects will be similar. For the halogens, the electron is added to an *np* subshell, so the energy change is likely to be quite different. (b) True. The electron configuration of H is $1s^1$. The single 1*s* electron experiences no repulsion from other electrons and feels the full unshielded nuclear charge. The outer electrons of all other elements that form compounds are shielded by a spherical inner core of electrons and are less strongly attracted to the nucleus, resulting in larger bonding atomic radii. (c) Both H and the halogens have large ionization energies. The relatively large effective nuclear charge experienced by *np* electrons of the halogens is similar to the unshielded nuclear charge experienced by the H 1*s* electron. For the alkali metals, the *ns* electron being removed is effectively shielded by the core electrons, so ionization energies are low. (d) ionization energy of hydride, $H^-(g) \longrightarrow H(g) + 1e^-$ (e) electron affinity of hydrogen, $H(g) + 1\,e^- \longrightarrow H^-(g)$. The value for the ionization energy of hydride is equal in magnitude but opposite in sign to the electron affinity of hydrogen. **7.102** The most likely product is (i). **7.107** Electron configuration, $[Rn]7s^25f^{14}6d^{10}7p^5$; first ionization energy, 805 kJ/mol; electron affinity, −235 kJ/mol; atomic size, 1.65 Å; common oxidation state, −1. **7.110** (a) Li, $[He]2s^1$; $Z_{eff} \approx 1+$ (b) $I_1 \approx 5.45 \times 10^{-19}$ J/atom $\approx$ 328 kJ/mol (c) The estimated value of 328 kJ/mol is less than the Table 7.4 value of 520 kJ/mol. Our estimate for Z_{eff} was a lower limit; the [He] core electrons do not perfectly shield the 2*s* electron from the nuclear charge. (d) Based on the experimental ionization energy, $Z_{eff} = 1.26$. This value is greater than the estimate from part (a) but agrees well with the "Slater" value of 1.3 and is consistent with the explanation in part (c). **7.113** (a) Mg_3N_2 (b) $Mg_3N_2(s) + 3\,H_2O(l) \longrightarrow 3\,MgO(s) + 2\,NH_3(g)$; the driving force is the production of $NH_3(g)$. (c) 17% Mg_3N_2 (d) $3\,Mg(s) + 2\,NH_3(g) \longrightarrow Mg_3N_2(s) + 3\,H_2(g)$. NH_3 is the limiting reactant and 0.46 g H_2 is formed. (e) $\Delta H^\circ_{rxn} = -368.70$ kJ

Chapter 8

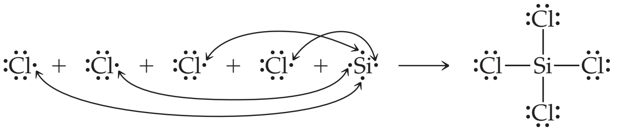
8.1 (a) Group 4A or 14 (b) Group 2A or 2 (c) Group 5A or 15 **8.4** (a) Ru (b) $[Kr]5s^24d^6$. **8.7** (a) Four (b) In order of increasing bond length: $3 < 1 < 2$ (c) In order of increasing bond enthalpy: $2 < 1 < 3$ **8.9** (a) False (b) A nitrogen atom has 5 valence electrons. (c) The atom (Si) has 4 valence electrons. **8.11** (a) Si, $1s^22s^22p^63s^23p^2$ (b) four (c) The 3*s* and 3*p* electrons are valence electrons.

8.13

8.15

(b) two (c) Mg loses electrons. **8.17** (a) AlF_3 (b) K_2S (c) Y_2O_3 (d) Mg_3N_2 **8.19** (a) Sr^{2+}, $[Ar]4s^23d^{10}4p^6 = [Kr]$, noble-gas configuration (b) Ti^{2+}, $[Ar]3d^2$ (c) Se^{2-}, $[Ar]4s^23d^{10}4p^6 = [Kr]$, noble-gas configuration (d) Ni^{2+}, $[Ar]3d^8$ (e) Br^-, $[Ar]4s^23d^{10}4p^6 = [Kr]$, noble-gas configuration (f) Mn^{3+}, $[Ar]3d^4$ **8.21** (a) Endothermic (b) $NaCl(s) \longrightarrow Na^+(g) + Cl^-(g)$ (c) Salts like CaO that have doubly charged ions will have larger lattice energies compared with salts that have singly charged ions **8.23** (a) The slope of this line is 3.32×10^3 kJ/cation charge (b) The slope of this line is 829 kJ/(cation charge)^2 (c) The data points fall much closer to the line on the graph of lattice energy versus the square of the cation charge. The trend of lattice energy versus the square of the cation charge is more linear. (d) The lattice energy of TiC should be 1.34×10^4 kJ **8.25** (a) K–F, 2.71 Å; Na–Cl, 2.83 Å; Na–Br, 2.98 Å; Li–Cl, 2.57 Å (b) LiCl > KF > NaCl > NaBr (c) From Table 8.2: LiCl, 1030 kJ; KF, 808 kJ; NaCl, 788 kJ; NaBr, 732 kJ. The predictions from ionic radii are correct. **8.27** Statement (a) is the best explanation. **8.29** The lattice energy of RbCl(*s*) is +692 kJ/mol. **8.31** (a) The bonding in (iii) and (iv) is likely to be covalent. (b) Covalent, because it is a gas at room temperature and below.

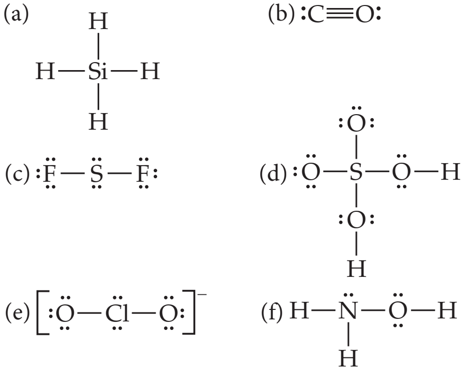
8.33



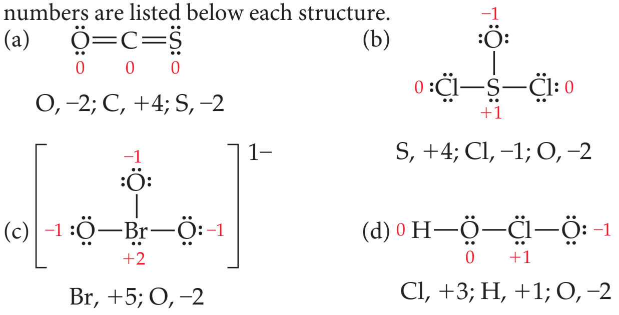
(a) 4 (b) 7 (c) 8 (d) 8 (e) 4 **8.35** (a)

(b) four bonding electrons (two bonding electron pairs) (c) An O═O double bond is shorter than an O—O single bond. The greater the number of shared electron pairs between two atoms, the shorter the distance between the atoms. **8.37** Statement (b) is false. **8.39** (a) Mg (b) S (c) C (d) As **8.41** The bonds in (a), (c), and (d) are polar. The more electronegative element in each polar bond is (a) F (c) O (d) I. **8.43** (a) The calculated charge on H and Br is 0.12*e*. (b) Decrease **8.45** (a) SiF_4, molecular, silicon tetrachloride; LaF_3, ionic, lanthanum(III) fluoride (b) $FeCl_2$, ionic, iron(II) chloride; $ReCl_6$, molecular (metal in high oxidation state), rhenium hexachloride. (c) $PbCl_4$, molecular (by contrast to the distinctly ionic RbCl), lead tetrachloride; RbCl, ionic, rubidium chloride

8.47



8.49 Statement (b) is most true. Keep in mind that when it is necessary to place more than an octet of electrons around an atom in order to minimize formal charge, there may not be a "best" Lewis structure. **8.51** Formal charges are shown on the Lewis structures; oxidation numbers are listed below each structure.



(a) O, −2; C, +4; S, −2

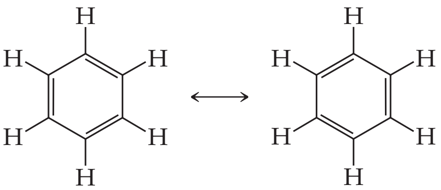
(b) S, +4; Cl, −1; O, −2

(c) Br, +5; O, −2

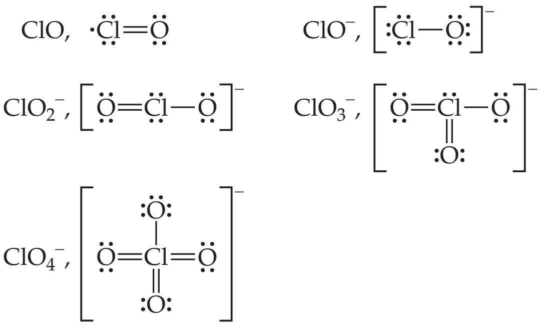
(d) Cl, +3; H, +1; O, −2

8.53 (a)

(b) O_3 is isoelectronic with NO_2^-; both have 18 valence electrons. (c) Since each N—O bond has partial double-bond character, the N—O bond length in NO_2^- should be shorter than an N—O single bond but longer than an N═O double bond. **8.55** The more electron pairs shared by two atoms, the shorter the bond. Thus, the C—O bond lengths vary in the order $CO < CO_2 < CO_3^{2-}$. **8.57** (a) No. Two equally valid Lewis structures can be drawn for benzene.



The concept of resonance dictates that the true description of bonding is some hybrid or blend of these two Lewis structures. The most obvious blend of these two resonance structures is a molecule with six equivalent C—C bonds with equal lengths. (b) Yes. This model predicts a uniform C—C bond length that is shorter than a single bond but longer than a double bond. (b) No. The C—C bonds in benzene have some double bond character but they are not full double bonds. They are longer than isolated C═C double bonds. **8.59** (a) True (b) False (c) True (d) False **8.61** Assume that the dominant structure is the one that minimizes formal charge. Following this guideline, only ClO^- obeys the octet rule. ClO, ClO_2^-, ClO_3^-, and ClO_4^- do not obey the octet rule.

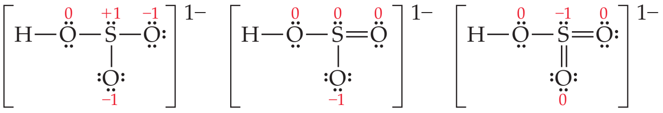


8.63 (a)  (b) 
(b) Does not obey the octet rule. Central Al has only 6 electrons

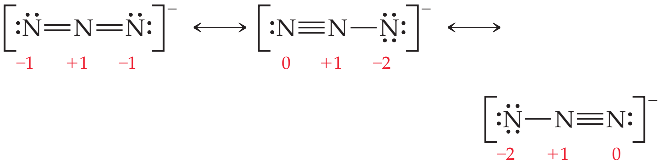
(c) 
(d)  (e) 
(e) Does not obey octet rule. Central Sn has 12 electrons.

8.65 (a) 
This structure violates the octet rule.

(b) 
(c) Formal charges are minimized on the structure that violates the octet rule; this form is probably dominant. **8.67** Three resonance structures for HSO_3^- are shown here. Because the ion has a 1− charge, the sum of the formal charges of the atoms is −1.



The structure with no double bonds obeys the octet rule for all atoms, but does not lead to minimized formal charges. The structures with one and two double bonds both minimize formal charge but do not obey the octet rule. Of these two, the structure with one double bond is preferred because the formal charge is localized on the more electronegative oxygen atom. **8.69** (a) $\Delta H = -304$ kJ (b) $\Delta H = -82$ kJ (c) $\Delta H = -467$ kJ **8.71** (a) $\Delta H = -321$ kJ (b) $\Delta H = -103$ kJ (c) $\Delta H = -203$ kJ **8.73** (a) ΔH calculated from bond enthalpies is −97 kJ; the reaction is exothermic. (b) The ΔH calculated from ΔH_f° values is −92.38 kJ. **8.75** The average Ti—Cl bond enthalpy is 430 kJ/mol. **8.77** (a) Seven elements in the periodic table have Lewis symbols with single dots. They are in Group 1A, the alkali metals. This includes hydrogen, whose placement is problematic, and francium, which is radioactive. **8.81** The charge on M is likely to be 3+. The range of lattice energies for ionic compounds with the general formula MX and a charge of 2+ on the metal is 3-4 × 10^3 kJ/mol. The lattice energy of 6 × 10^3 kJ/mol indicates that the charge on M must be greater than 2+. **8.85** (a) B—O. The most polar bond will be formed by the two elements with the greatest difference in electronegativity. (b) Te—I. These elements have the two largest covalent radii among this group. (c) TeI_2 The octet rule is satisfied for all three atoms. (d) P_2O_3. Each P atom needs to share 3 e^- and each O atom 2 e^- to achieve an octet. And B_2O_3. Although this is not a purely ionic compound, it can be understood in terms of gaining and losing electrons to achieve a noble-gas configuration. If each B atom were to lose 3 e^- and each O atom were to gain 2 e^-, charge balance and the octet rule would be satisfied. **8.90** (a) +1 (b) −1 (c) +1 (assuming the odd electron is on N) (d) 0 (e) +3 **8.95** (a) False. The B—A=B structure says nothing about the nonbonding electrons in the molecule. (b) True **8.98** (a) $\Delta H = 7.85$ kJ/g nitroglycerine (b) $4\,C_7H_5N_3O_6(s) \longrightarrow 6\,N_2(g) + 7\,CO_2(g) + 10\,H_2O(g) + 21\,C(s)$ **8.101** (a) Ti^{2+}, $[Ar]3d^2$; Ca, $[Ar]4s^2$. (b) Ca has no unpaired electrons and Ti^{2+} has two. (c) In order to be isoelectronic with Ca^{2+}, Ti would have a 4+ charge. **8.107** (a) Azide ion is N_3^-. (b) Resonance structures with formal charges are shown.

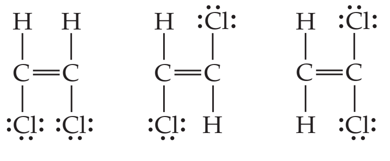


(c) The structure with two double bonds minimizes formal charges and is probably the main contributor. (d) The N—N distances will be equal and have the approximate length of a N—N double bond, 1.24 Å. **8.112** (a) $D(Br—Br)(l) = 223.6$ kJ; $D(Br—Br)(g) = 193$ kJ (b) $D(C—Cl)(l) = 336.1$ kJ; $D(C - Cl)(g) = 328$ kJ (c) $D(O—O)(l) = 192.7$ kJ; $D(O—O)(g) = 146$ kJ (d) Breaking bonds in the liquid requires more energy than breaking bonds in the gas phase. Bond dissociation in the liquid phase can be thought of in two steps, vaporization of the liquid followed by bond dissociation in the gas phase. The greater bond dissociation enthalpy in the liquid phase is due to the contribution from the enthalpy of vaporization.

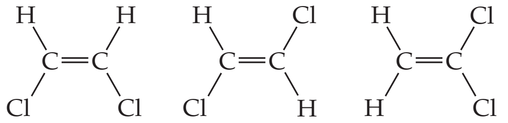
Chapter 9

9.1 Removing an atom from the equatorial plane of the trigonal bipyramid in Figure 9.3 creates a seesaw shape. **9.3** (a) Two electron-domain geometries, linear and trigonal bipyramidal (b) one electron-domain geometry, trigonal bipyramidal (c) one electron-domain geometry, octahedral (c) one electron-domain geometry, octahedral (d) one electron domain geometry, octahedral (e) one electron domain geometry, octahedral (f) one electron-domain geometry, trigonal bipyramidal (This triangular pyramid is an unusual molecular geometry not listed in Table 9.3. It could occur if the equatorial substituents on the trigonal bipyramid were extremely bulky, causing the nonbonding electron pair to occupy an axial position.) **9.5** (a) Zero energy corresponds to two separate, noninteracting Cl atoms. This infinite Cl—Cl distance is beyond the right extreme of the horizontal axis on the diagram. (b) According to the valence bond model, valence orbitals on the approaching atoms overlap, allowing two electrons to mutually occupy space between the two nuclei and be stabilized by two nuclei rather than one. (c) The Cl—Cl distance at the energy minimum on the plot is the Cl—Cl bond length. (d) At interatomic separations shorter than the bond distance, the two nuclei begin to repel each other, increasing the overall energy of the system. (e) The *y*-coordinate of the minimum point on the plot is a good estimate of the Cl—Cl bond energy or bond strength. **9.11** (a) i, Two *s* atomic orbitals; two *p* atomic orbitals overlapping end to end; two *p* atomic orbitals overlapping side to side (b) i, σ-type MO; ii, σ-type MO; iii, π-type MO (c) i, antibonding; ii, bonding; iii, antibonding (d) i, the nodal plane is between the atom centers, perpendicular to the interatomic axis and equidistant from each atom. ii, there are two nodal planes; both are perpendicular to the interatomic axis. One is left of the left atom and the second is right of the right atom. iii, there are two nodal planes; one is between the atom centers, perpendicular to the interatomic axis and equidistant from each atom. The second contains the interatomic axis and is perpendicular to the first. **9.13** (a) Yes. The stated shape defines the bond angle and the bond length tells the size. (b) No. Atom A could have 2, 3, or 4 nonbonding electron pairs. **9.15** A molecule with tetrahedral molecular geometry has an atom at each vertex of the tetrahedron. A trigonal-pyramidal molecule has one vertex of the tetrahedron occupied by a nonbonding electron pair rather than an atom. **9.17** (a) The number of electron domains in a molecule or ion is the number of bonds (double and triple bonds count as one domain) plus the number of nonbonding electron pairs. (b) A *bonding electron domain* is a region between two bonded atoms that contains one or more pairs of bonding electrons. A *nonbonding electron domain* is localized on a single atom and contains one pair of nonbonding electrons. **9.19** (a) No effect on molecular shape (b) 1 nonbonding pair on P influences molecular shape (c) no effect (d) no effect (e) 1 nonbonding pair on S influences molecular shape **9.21** (a) 2 (b) 1 (c) none (d) 3 **9.23** (a) Tetrahedral, tetrahedral (b) trigonal bipyramidal, T-shaped (c) octahedral, square pyramidal (d) octahedral, square planar **9.25** (a) Linear, linear (b) tetrahedral, trigonal pyramidal (c) trigonal bipyramidal, seesaw (d) octahedral, octahedral (e) tetrahedral, tetrahedral (f) linear, linear **9.27** (a) i, trigonal planar; ii, tetrahedral; iii, trigonal bipyramidal (b) i, 0; ii, 1; iii, 2 (c) N and P (d) Cl (or Br or I). This T-shaped molecular geometry arises from a trigonal-bipyramidal electron-domain geometry with 2 nonbonding domains. Assuming each F atom has 3 nonbonding domains and forms only single bonds with A, A must have 7 valence electrons and be in or below the third row of the periodic table to produce these electron-domain and molecular geometries. **9.29** (a) 1, less than 109.5°; 2, less than 109.5° (b) 3, different than 109.5°; 4, less than 109.5° (c) 5, 180° (d) 6, slightly more than 120°; 7, less than 109.5°; 8, different than 109.5° **9.31** Each species has four electron domains around the N atom, but the number of nonbonding domains decreases from two to zero, going from NH_2^- to NH_4^+. Since nonbonding domains exert greater repulsive forces on adjacent domains, the bond angles expand as the number of nonbonding domains decreases. **9.33** (a) Although both ions have 4 bonding electron domains, the 6 total domains around Br require octahedral domain geometry and square-planar molecular geometry, while the 4 total domains about B lead to tetrahedral domain and molecular geometry. (b) The angles will vary as $H_2O > H_2S > H_2Se$. The less electronegative the central atom, the larger the nonbonding electron domain, and the greater the effect of repulsive forces on adjacent bonding domains. The less electronegative the central atom, the greater the deviation from ideal tetrahedral angles. **9.35** A bond dipole is the asymmetric charge distribution between two bonded atoms with unequal electronegativities. A molecular dipole moment is the three-dimensional sum of all the bond dipoles in a molecule. **9.37** (a) Yes. The net dipole moment vector points along the Cl—S—Cl angle bisector. (b) No, $BeCl_2$ does not have a dipole moment. **9.39** (a) For a molecule with polar bonds to be nonpolar, the polar bonds must be (symmetrically) arranged so that the bond dipoles cancel. Any nonbonding pairs about the central atom must be arranged so that they also cancel. In most cases, nonbonding electron domains will be absent from the central atom. (b) AB_2, linear electron domain and molecular geometry, trigonal bipyramidal electron domain geometry and linear molecular geometry; AB_3, trigonal planar electron domain and molecular geometry; AB_4, tetrahedral electron domain and molecular geometry, octahedral electron domain geometry and square planar molecular geometry **9.41** (a) IF (d) PCl_3 and (f) IF_5 are polar.

9.43 (a) Lewis structures



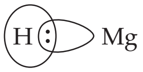
Molecular geometries



Polar Nonpolar Polar

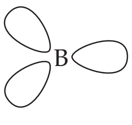
(b) The middle isomer has a zero net dipole moment. (c) C_2H_3Cl has only one isomer, and it has a dipole moment. **9.45** (a) *Orbital overlap* occurs when valence atomic orbitals on two adjacent atoms share the same region of space. (b) A chemical bond is a concentration of electron density between the nuclei of two atoms. This concentration can take place because orbitals on the two atoms overlap. **9.47** (a) H—Mg—H, linear electron domain and molecular geometry (b) The linear electron-domain geometry in MgH_2 requires *sp* hybridization.

(c)



9.49 (a) B, [He]$2s^22p^1$. One 2*s* electron is "promoted" to an empty 2*p* orbital. The 2*s* and two 2*p* orbitals that each contain one electron are hybridized to form three equivalent hybrid orbitals in a trigonal-planar arrangement. (b) sp^2

(c)



(d) A single 2*p* orbital is unhybridized. It lies perpendicular to the trigonal plane of the sp^2 hybrid orbitals. **9.51** (a) sp^2 (b) sp^3 (c) sp (d) sp^3 **9.53** Left, no hybrid orbitals discussed in this chapter form angles of 90° with each other; *p* atomic orbitals are perpendicular to each other. center, 109.5°, sp^3; right, 120°, sp^2

9.55 (a)

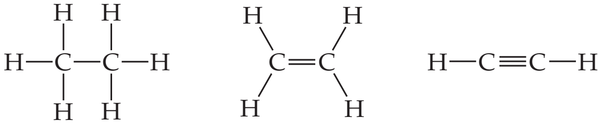
σ

(b)

π

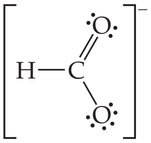
(c) A σ bond is generally stronger than a π bond because there is more extensive orbital overlap. (d) No. Overlap of two *s* orbitals results in electron density along the internuclear axis, while a π bond has none.

9.57 (a)



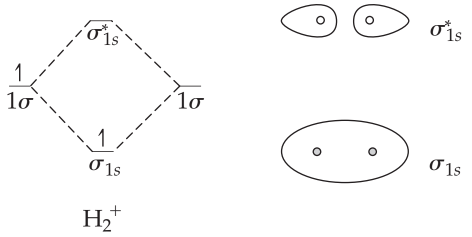
(b) sp^3, sp^2, sp (c) nonplanar, planar, planar (d) 7 σ, 0 π; 5 σ, 1 π; 3 σ, 2 π **9.59** (a) 18 valence electrons (b) 16 valence electrons form σ bonds. (c) 2 valence electrons form π bonds. (d) No valence electrons are nonbonding. (e) The left and central C atoms are sp^2 hybridized; the right C atom is sp^3 hybridized. **9.61** (a) ~109.5° about the leftmost C, sp^3; ~120° about the right-hand C, sp^2 (b) The doubly bonded O can be viewed as sp^2, and the other as sp^3; the nitrogen is sp^3 with bond angles less than 109.5°. (c) nine σ bonds, one π bond **9.63** (a) In a localized π bond, the electron density is concentrated between the two atoms forming the bond. In a delocalized π bond, the electron density is spread over all the atoms that contribute *p* orbitals to the network. (b) The existence of more than one resonance form is a good indication that a molecule will have delocalized π bonding. (c) delocalized

9.65 (a)



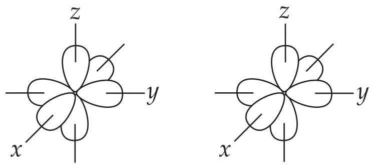
(b) sp^2 (c) Yes, there is one other resonance structure. (d) The C and two O atoms have p_π orbitals. (e) There are four electrons in the π system of the ion. **9.67** (a) Linear (b) The two central C atoms each have trigonal planar geometry with ~120° bond angles about them. The C and O atoms lie in a plane with the H atoms free to rotate in and out of this plane. (c) The molecule is planar with ~120° bond angles about the two N atoms. **9.69** (a) Hybrid orbitals are mixtures of atomic orbitals from a single atom and remain localized on that atom. Molecular orbitals are combinations of atomic orbitals from two or more atoms and are delocalized over at least two atoms. (b) Each MO can hold a maximum of two electrons. (c) Antibonding molecular orbitals can have electrons in them.

9.71 (a)



(b) There is one electron in H_2^+. (c) σ_{1s}^1 (d) BO $= \frac{1}{2}$ (e) Fall apart. If the single electron in H_2^+ is excited to the σ_{1s}^* orbital, its energy is higher than the energy of an H 1*s* atomic orbital and H_2^+ will decompose into a hydrogen atom and a hydrogen ion. (f) Statement (i) is correct.

9.73



(a) 1 σ bond (b) 2 π bonds (c) 1 σ^* and 2 π^* **9.75** (a) When comparing the same two bonded atoms, bond order and bond energy are directly related, while bond order and bond length are inversely related. When comparing different bonded nuclei, there are no simple relationships. (b) Be_2 is not expected to exist; it has a bond order of zero and is not energetically favored over isolated Be atoms. Be_2^+ has a bond order of 0.5 and is slightly lower in energy than isolated Be atoms. It will probably exist under special experimental conditions. **9.77** (a, b) Substances with no unpaired electrons are weakly repelled by a magnetic field. This property is called *diamagnetism*. (c) O_2^{2-}, Be_2^{2+} **9.79** (a) B_2^+, $\sigma_{2s}^2\sigma_{2s}^{*2}\pi_{2p}^1$, increase (b) Li_2^+, $\sigma_{1s}^2\sigma_{1s}^{*2}\sigma_{2s}^1$, increase (c) N_2^+, $\sigma_{2s}^2\sigma_{2s}^{*2}\pi_{2p}^4\sigma_{2p}^1$, increase (d) Ne_2^{2+}, $\sigma_{2s}^2\sigma_{2s}^{*2}\sigma_{2p}^2\pi_{2p}^4\pi_{2p}^{*4}$, decrease **9.81** CN, $\sigma_{2s}^2\sigma_{2s}^{*2}\sigma_{2p}^2\pi_{2p}^3$, bond order $= 2.5$; CN^+, $\sigma_{2s}^2\sigma_{2s}^{*2}\sigma_{2p}^2\pi_{2p}^2$, bond order $= 2.0$; CN^-, $\sigma_{2s}^2\sigma_{2s}^{*2}\sigma_{2p}^2\pi_{2p}^4$, bond order $= 3.0$. (a) CN^- (b) CN, CN^+ **9.83** (a) 3*s*, $3p_x$, $3p_y$, $3p_z$ (b) π_{3p} (c) 2 (d) If the MO diagram for P_2 is similar to that of N_2, P_2 will have no unpaired electrons and be diamagnetic. **9.87** (a) PF_4^-, BrF_4^- and ClF_4^- (b) AlF_4^- (c) BrF_4^- (d) PF_4^- and ClF_4^+

9.90

Molecule	Electron-Domain Geometry	Hybridization of Central Atom	Dipole Moment? Yes or No
CO_2	Linear	*sp*	No
NH_3	Tetrahedral	sp^3	Yes
CH_4	Tetrahedral	sp^3	No
BH_3	Trigonal planar	sp^2	No
SF_4	Trigonal bipyramidal	Not applicable	Yes

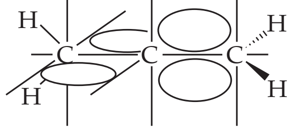
XeF_2	Trigonal bipyramidal	Not applicable	No

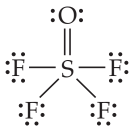
9.91 (a) 2 σ bonds, 2 π bonds (b) 3 σ bonds, 4 π bonds (c) 3 σ bonds, 1 π bond (d) 4 σ bonds, 1 π bond

9.98



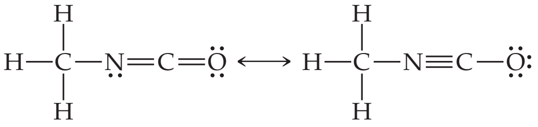
(a) The molecule is nonplanar. (b) Allene has no dipole moment. (c) The bonding in allene would not be described as delocalized. The π electron clouds of the two adjacent C═C are mutually perpendicular, so there is no overlap and no delocalization of π electrons. **9.101** (a) All O atoms have sp^2 hybridization. (b) The two σ bonds are formed by overlap of sp^2 hybrid orbitals, the π bond is formed by overlap of atomic *p* orbitals, one nonbonded pair is in a *p* atomic orbital and the other five nonbonded pairs are in sp^2 hybrid orbitals. (c) unhybridized *p* atomic orbitals (d) four, two from the π bond and two from the nonbonded pair in the *p* atomic orbital **9.104** The silicon analogs would have the same hybridization as the C compounds. Silicon, which is in the row below C, has a larger bonding atomic radius and atomic orbitals than C. The close approach of Si atoms required to form strong, stable π bonds in Si_2H_4 and Si_2H_2 is not possible and these Si analogs do not readily form. **9.108** $\sigma_{2s}^2\sigma_{2s}^{*2}\pi_{2p}^4\sigma_{2p}^1\pi_{2p}^{*1}$ (a) Paramagnetic (b) The bond order of N_2 in the ground state is 3; in the first excited state it has a bond order of 2. Owing to the reduction in bond order, N_2 in the first excited state has a weaker N—N bond. **9.114** (a) $2\ SF_4(g) + O_2(g) \longrightarrow 2\ OSF_4(g)$

(b)



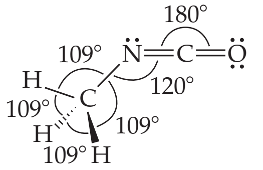
(c) $\Delta H = -551$ kJ, exothermic (d) The electron-domain geometry is trigonal bipyramidal. The O atom can be either equatorial or axial. (e) Because F is more electronegative than O, S–F bonding domains are smaller than the S═O domain. The structure that minimizes S═O repulsions has O in the equatorial position and is more likely. **9.118** ΔH from bond enthalpies is 5364 kJ; ΔH from ΔH_f° values is 5535 kJ. The difference in the two results, 171 kJ/mol C_6H_6, is due to the resonance stabilization in benzene. Because the π electrons are delocalized, the molecule has a lower overall energy than that predicted using bond enthalpies for localized C—C and C═C bonds. Thus, the amount of energy actually required to decompose 1 mole of $C_6H_6(g)$, represented by the Hess' law calculation, is greater than the sum of the localized bond enthalpies.

9.122 (a)



(The structure on the right does not minimize formal charges and will make a minor contribution to the true structure.)

(b)



Both resonance structures predict the same bond angles.
(c) The two extreme Lewis structures predict different bond lengths. These bond length estimates assume that the structure minimizing formal charge makes a larger contribution to the true structure. C—O, 1.28 Å; C═N, 1.33 Å; C—N, 1.43 Å; C—H, 1.07 Å (d) The molecule will have a dipole moment. The C═N and C═O bond dipoles are opposite each other, but they are not equal. And, there are nonbonding electron pairs that are not directly opposite each other and will not cancel.

Chapter 10

10.1 It would be much easier to drink from a straw on Mars. When a straw is placed in a glass of liquid, the atmosphere exerts equal pressure inside and outside the straw. When we drink through a straw, we withdraw air, thereby reducing the pressure on the liquid inside. If only 0.007 atm is exerted on the liquid in the glass, a very small reduction in pressure inside the straw will cause the liquid to rise. **10.3** At the same temperature, volume and the lower pressure, the container would have half as many particles as at the higher pressure. **10.5** For a fixed amount of ideal gas at constant volume, if the pressure is doubled, the temperature also doubles. **10.7** (a) $P_{red} < P_{yellow} < P_{blue}$ (b) $P_{red} = 0.28$ atm; $P_{yellow} = 0.42$ atm; $P_{blue} = 0.70$ atm **10.09** (a) Curve B is helium. (b) Curve B corresponds to the higher temperature. (c) The root mean square speed is highest. **10.11** The $NH_4Cl(s)$ ring will form at location A. **10.13** (a) A gas is much less dense than a liquid. (b) A gas is much more compressible than a liquid. (c) All mixtures of gases are homogenous. Similar liquid molecules form homogeneous mixtures, while very dissimilar molecules form heterogeneous mixtures. (d) Both gases and liquids conform to the shape of their container. A gas also adopts the volume of its container, while a liquid maintains its own volume. **10.15** (a) 1.8×10^3 kPa (b) 18 atm (c) 2.6×10^2 lb/in.^{2} **10.17** (a) 10.3 m (b) 2.1 atm **10.19** (a) 0.349 atm (b) 265 mm Hg (c) 3.53×10^4 Pa (d) 0.353 bar (e) 5.13 psi **10.21** (a) $P = 773.4$ torr (b) $P = 1.018$ atm (c) The pressure in Chicago is greater than standard atmospheric pressure, and so it makes sense to classify this weather system as a "high-pressure system." **10.23** (i) 0.31 atm (ii) 1.88 atm (iii) 0.136 atm **10.25** The action in (c) would double the pressure **10.27** (a) Boyle's Law, $PV =$ constant or $P_1V_1 = P_2V_2$, at constant V, $P_1/P_2 = 1$; Charles' Law, $V/T =$ constant or $V_1/T_1 = V_2/T_2$, at constant V, $T_1/T_2 = 1$; then $P_1/T_1 = P_2/T_2$ or $P/T =$ constant. Amonton's law is that pressure and Kelvin temperature are directly proportional at constant volume. (b) 34.7 psi **10.29** (a) STP stands for standard temperature, 0 °C (or 273 K), and standard pressure, 1 atm. (b) 22.4 L (c) 24.5 L (d) 0.08315 L-bar/mol-K **10.31** Flask A contains the gas with a molar mass of 30 g/mol and flask B contains the gas with a molar mass of 60 g/mol.

10.33

P	*V*	*n*	*T*
200 atm	1.00 L	0.500 mol	48.7 K
0.300 atm	0.250 L	3.05×10^{-3} mol	27 °C
650 torr	11.2 L	0.333 mol	350 K
10.3 atm	585 mL	0.250 mol	295 K

10.35 8.2×10^2 kg He **10.37** (a) 5.15×10^{22} molecules (b) 6.5 kg air **10.39** (a) 91 atm (b) 2.3×10^2 L **10.41** $P = 4.9$ atm **10.43** (a) 29.8 g Cl_2 (b) 9.42 L (c) 501 K (d) 2.28 atm **10.45** (a) $n = 2 \times 10^{-4}$ mol O_2 (b) The roach needs 8×10^{-3} mol O_2 in 48 h, approximately 100% of the O_2 in the jar. **10.47** For gas samples at the same conditions, molar mass determines density. Of the three gases listed, (c) Cl_2 has the largest molar mass. **10.49** (c) Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The balloon thus weighs less than the air displaced by its volume. **10.51** (a) $d = 1.77$ g/L (b) molar mass $= 80.1$ g/mol **10.53** molar mass $= 89.4$ g/mol **10.55** 4.1×10^{-9} g Mg **10.57** (a) 21.4 L CO_2 (b) 40.7 L O_2 **10.59** 0.402 g Zn **10.61** (a) When the stopcock is opened, the volume occupied by $N_2(g)$ increases from 2.0 L to 5.0 L. $P_{N_2} = 0.40$ atm (b) When the gases mix, the volume of $O_2(g)$ increases from 3.0 L to 5.0 L. $P_{O_2} = 1.2$ atm (c) $P_t = 1.6$ atm **10.63** (a) $P_{He} = 1.87$ atm, $P_{Ne} = 0.807$ atm, $P_{Ar} = 0.269$ atm, (b) $P_t = 2.95$ atm **10.65** $X_{CO_2} = 0.00039$ **10.67** $P_{CO_2} = 0.305$ atm, $P_t = 1.232$ atm **10.69** $P_{CO_2} = 0.9$ atm **10.71** 2.5 mole % O_2 **10.73** $P_t = 2.47$ atm **10.75** (a) Decrease (b) increase (c) decrease **10.77** The two common assumptions are: (i) the volume of gas molecules is negligible relative to the container volume; and (ii) attractive and repulsive forces among molecules are negligible. **10.79** The root-mean-square speed of WF_6 is approximately 8 times slower than that of He. **10.81** (a) Average kinetic energy of the molecules increases. (b) Root mean square speed of the molecules increases. (c) Strength of an average impact with the container walls increases. (d) Total collisions of molecules with walls per second increases. **10.83** (a) In order of increasing speed and decreasing molar mass: HBr < NF_3 < SO_2 < CO < Ne (b) $u_{NF_3} = 324$ m/s (c) The most probable speed of an ozone molecule in the stratosphere is 306 m/s. **10.85** Effusion is the escape of gas molecules through a tiny hole. Diffusion is the distribution of a gas throughout space or throughout another substance. **10.87** The order of increasing rate of effusion is ${}^2H^{37}Cl < {}^1H^{37}Cl < {}^2H^{35}Cl < {}^1H^{35}Cl$. **10.89** As_4S_6 **10.91** (a) Non-ideal-gas behavior is observed at very high pressures and low temperatures. (b) The real volumes of gas molecules and attractive intermolecular forces between molecules cause gases to behave nonideally. **10.93** Ar ($a = 1.34$, $b = 0.0322$) will behave more like an ideal gas than CO_2 ($a = 3.59$, $b = 0.427$) at high pressures. **10.95** (a) $P = 4.89$ atm (b) $P = 4.69$ atm (c) Qualitatively, molecular attractions are more important as the amount of free space decreases and the number of molecular collisions increases. Molecular volume is a larger part of the total volume as the container volume decreases. **10.97** From the value of b for Xe, the nonbonding radius is 2.72 Å. From Figure 7.7, the bonding atomic radius of Xe is 1.40 Å. We expect the bonding radius of an atom to be smaller than its nonbonding radius, but our claculated value is nearly twice as large. **10.99** $V = 3.1$ mm^3 **10.101** $P = 0.43$ mm Hg **10.103** (a) 13.4 mol $C_3H_8(g)$ (b) 1.47×10^3 mol $C_3H_8(l)$ (c) The ratio of moles liquid to moles gas is 110. Many more molecules and moles of liquid fit in a container of fixed volume because there is much less space between molecules in the liquid phase. **10.105** (a) Molar mass of the unknown gas is 100.4 g/mol (b) We assume that the gases behave ideally, and that P, V and T are constant. **10.107** (a) 0.00378 mol O_2 (b) 0.0345 g C_8H_8 **10.109** 42.2 g O_2 **10.111** (a) Molar mass of the unknown gas is 50.46 g/mol (b) The ratio d/P varies with pressure because of the finite volumes of gas molecules and attractive intermolecular forces. **10.113** $T_2 = 687$ °C **10.115** (a) More significant (b) less significant **10.117** (a) At STP, argon atoms occupy 0.0359% of the total volume. (b) At 200 atm pressure and 0 °C, argon atoms occupy 7.19% of the total volume. **10.119** (a) The molecular formula of cyclopropane is C_3H_6. (b) Although the molar masses of Ar and C_3H_6 are similar, we expect intermolecular attractions to be more significant for the more complex C_3H_6 molecules, and that C_3H_6 will deviate more from ideal behavior at the conditions listed. If the pressure is high enough for the volume correction in the van der Waals equation to dominate behavior, the larger C_3H_6 molecules definitely deviate more than Ar atoms from ideal behavior. (c) Cyclopropane would effuse through a pinhole slower than methane, because it has the greater molar mass. **10.121** (a) 44.58% C, 6.596% H, 16.44% Cl, 32.38% N (b) $C_8H_{14}N_5Cl$ (c) Molar mass of the compound is required in order to determine molecular formula when the empirical formula is known. **10.123** (a) $NH_3(g)$ remains after reaction. (b) $P = 0.957$ atm (c) 7.33 g NH_4Cl **10.125** (a) 
(b) ClO_2 is very reactive because it is an odd-electron molecule. Adding an electron both pairs the odd electron and completes the octet of Cl. ClO_2 has a strong tendency to gain an electron and be reduced.

(c) 
(d) The bond angle is approximately 170°. (e) 11.2 g ClO_2 **10.127** (a) $P_{IF_3} = 0.515$ atm (b) $X_{IF_5} = 0.544$

(c) 
(d) Total mass in the flask is 20.00 g; mass is conserved.

Chapter 11

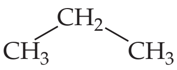
11.1 (a) The diagram best describes a liquid. (b) In the diagram, particles are close together, mostly touching, but there is no regular arrangement or order. This rules out a gaseous sample, where the particles are far apart, and a crystalline solid, which has a regular repeating structure in all three directions. **11.4** (a) In its final state, methane is a gas at 185 °C. **11.6** The stronger the intermolecular forces, the higher the boiling point of a liquid. Propanol, $CH_3CH_2CH_2OH$, has hydrogen bonding and the higher boiling point. **11.9** (a) Solid $<$ liquid $<$ gas (b) gas $<$ liquid $<$ solid (c) Matter in the gaseous state is most easily compressed because particles are far apart and there is much empty space. **11.11** (a) It increases. Kinetic energy is the energy of motion. As melting occurs, the motion of atoms relative to each other increases. (b) It increases somewhat. The density of liquid lead is less than the density of solid lead. The smaller density means a greater sample volume and average distance between atoms in three dimensions. **11.13** (a) The molar volumes of Cl_2 and NH_3 are nearly the same because they are both gases. (b) On cooling to 160 K, both compounds condense from the gas phase to the solid-state, so we expect a significant decrease in the molar volume. (c) The molar volumes are $0.0351\ L/mol\ Cl_2$ and $0.0203\ L/mol\ NH_3$ (d) Solid-state molar volumes are not as similar as those in the gaseous state, because most of the empty space is gone and molecular characteristics determine properties. $Cl_2(s)$ is heavier, has a longer bond distance and weaker intermolecular forces, so it has a significantly larger molar volume than $NH_3(s)$. (e) There is little empty space between molecules in the liquid state, so we expect their molar volumes to be closer to those in the solid state than those in the gaseous state. **11.15** (a) London dispersion forces (b) dipole–dipole forces (c) hydrogen bonding **11.17** (a) SO_2, dipole–dipole and London dispersion forces (b) CH_3COOH, London dispersion, dipole–dipole, and hydrogen bonding (c) H_2S, dipole–dipole and London dispersion forces (but not hydrogen bonding) **11.19** (a) *Polarizability* is the ease with which the charge distribution in a molecule can be distorted to produce a transient dipole. (b) Sb is most polarizable because its valence electrons are farthest from the nucleus and least tightly held. (c) in order of increasing polarizability: $CH_4 < SiH_4 < SiCl_4 < GeCl_4 < GeBr_4$ (d) The magnitudes of London dispersion forces and thus the boiling points of molecules increase as polarizability increases. The order of increasing boiling points is the order of increasing polarizability given in (c). **11.21** (a) H_2S (b) CO_2 (c) GeH_4 **11.23** Both rodlike butane molecules and spherical 2-methylpropane molecules experience dispersion forces. The larger contact surface between butane molecules facilitates stronger forces and produces a higher boiling point. **11.25** (a) A molecule must contain H atoms, bound to either N, O, or F atoms, in order to participate in hydrogen bonding with like molecules. (b) CH_3NH_2 and CH_3OH **11.27** (a) Replacing a hydroxyl hydrogen with a CH_3 group eliminates hydrogen bonding in that part of the molecule. This reduces the strength of intermolecular forces and leads to a lower boiling point. (b) $CH_3OCH_2CH_2OCH_3$ is a larger, more polarizable molecule with stronger London dispersion forces and thus a higher boiling point.

11.29

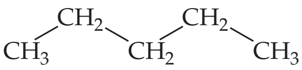
Physical Property	**H_2O**	**H_2S**
Normal boiling point, °C	100.00	−60.7
Normal melting point, C	0.00	−85.5

(a) Based on its much higher normal melting point and boiling point, H_2O has much stronger intermolecular forces. (b) H_2O has hydrogen bonding, while H_2S has dipole–dipole forces. Both molecules have London dispersion forces. **11.31** SO_4^{2-} has a greater negative charge than BF_4^-, so ion–ion electrostatic attractions are greater in sulfate salts and they are less likely to form liquids. **11.33** (a) As temperature increases, surface tension decreases; they are inversely related. (b) As temperature increases, viscosity decreases; they are inversely related. (c) The same attractive forces that cause surface molecules to be difficult to separate (high surface tension) cause molecules elsewhere in the sample to resist movement relative to each other (high viscosity). **11.35** (a) $CHBr_3$ has a higher molar mass, is more polarizable, and has stronger dispersion forces, so the surface tension is greater. (b) As temperature increases, the viscosity of the oil decreases because the average kinetic energy of the molecules increases. (c) Adhesive forces between polar water and nonpolar car wax are weak, so the large surface tension of water draws the liquid into the shape with the smallest surface area, a sphere. (d) Adhesive forces between nonpolar oil and nonpolar car wax are similar to cohesive forces in oil, so the oil drops spread out on the waxed car hood. **11.37** (a) The three molecules have similar structures and experience the same types of intermolecular forces. As molar mass increases, the strength of dispersion forces increases and the boiling points, surface tension, and viscosities all increase. (b) Ethylene glycol has an $-OH$ group at both ends of the molecule. This greatly increases the possibilities for hydrogen bonding; the overall intermolecular attractive forces are greater and the viscosity of ethylene glycol is much greater. (c) Water has the highest surface tension but lowest viscosity because it is the smallest molecule in the series. There is no hydrocarbon chain to inhibit their strong attraction to molecules in the interior of the drop, resulting in high surface tension. The absence of an alkyl chain also means the molecules can move around each other easily, resulting in the low viscosity. **11.39** (a) Melting, endothermic (b) evaporation, endothermic (c) deposition, exothermic (d) condensation, exothermic **11.41** Melting does not require separation of molecules, so the energy requirement is smaller than for vaporization, where molecules must be separated. **11.43** $2.3 \times 10^3\ g\,H_2O$ **11.45** (a) 39.3 kJ (b) 60 kJ **11.47** (a) The critical pressure is the pressure required to cause liquefaction at the critical temperature. (b) As the force of attraction between molecules increases, the critical temperature of the compound increases. (c) All the gases in Table 11.6 can be liquefied at the temperature of liquid nitrogen, given sufficient pressure. **11.49** Properties (c) intermolecular attractive forces, (d) temperature and (e) density of the liquid affect vapor pressure of a liquid. **11.51** (a) $CBr_4 < CHBr_3 < CH_2Br_2 < CH_2Cl_2 < CH_3Cl < CH_4$. (b) $CH_4 < CH_3Cl < CH_2Cl_2 < CH_2Br_2 < CHBr_3 < CBr_4$ (c) By analogy to attractive forces in HCl, the trend will be dominated by dispersion forces, even though four of the molecules are polar. The order of increasing boiling point is the order of increasing molar mass and increasing strength of dispersion forces. **11.53** (a) The temperature of the water in the two pans is the same. (b) Vapor pressure does not depend on either volume or surface area of the liquid. At the same temperature, the vapor pressures of water in the two containers are the same. **11.55** (a) Approximately 48 °C (b) approximately 340 torr (c) approximately 17 °C (d) approximately 1000 torr **11.57** (a) The critical point is the temperature and pressure beyond which the gas and liquid phases are indistinguishable. (b) The line that separates the gas and liquid phases ends at the critical point because at conditions beyond the critical temperature and pressure, there is no distinction between gas and liquid. In experimental terms a gas cannot be liquefied at temperatures higher than the critical temperature, regardless of pressure. **11.59** (a) $H_2O(g)$ will condense to $H_2O(s)$ at approximately 4 torr; at a higher pressure, perhaps 5 atm or so, $H_2O(s)$ will melt to form $H_2O(l)$. (b) At 100 °C and 0.50 atm, water is in the vapor phase. As it cools, water vapor condenses to the liquid at approximately 82 °C, the temperature where the vapor pressure of liquid water is 0.50 atm. Further cooling results in freezing at approximately 0 °C. The freezing point of water increases with decreasing pressure, so at 0.50 atm the freezing temperature is very slightly above 0 °C. **11.61** (a) 24 K (b) Neon sublimes at pressures less than the triple point pressure, 0.43 atm. (c) No **11.63** (a) Methane on the surface of Titan is likely to exist in both solid and liquid forms. (b) As pressure decreases upon moving away from the surface of Titan, $CH_4(l)$ (at −178 °C) will vaporize to $CH_4(g)$, and $CH_4(s)$ (at temperatures below −180 °C) will sublime to $CH_4(g)$. **11.65** In a nematic liquid crystalline phase, molecules are aligned along their long axes, but the molecular ends are not aligned. Molecules are free to translate in all dimensions, but they cannot tumble or rotate out of the molecular plane, or the order of the nematic phase is lost and the sample becomes an ordinary liquid. In an ordinary liquid, molecules are randomly oriented and free to move in any direction. **11.67** The presence of polar groups or nonbonded electron pairs leads to relatively strong dipole–dipole interactions between molecules. These are a significant part of the orienting forces necessary for liquid crystal formation. **11.69** Because order is maintained in at least one dimension, the molecules in a liquid-crystalline phase are not totally free to change orientation. This makes the liquid-crystalline phase more resistant to flow, more viscous, than the isotropic liquid. **11.71** Melting provides kinetic energy sufficient to disrupt molecular alignment in one dimension in the solid, producing a smectic phase with ordering in two dimensions. Additional heating of the smectic phase provides kinetic energy sufficient to disrupt alignment in another dimension, producing a nematic phase with one-dimensional order. **11.73** (a) Decrease (b) increase (c) increase (d) increase (e) increase (f) increase (g) increase **11.76** (a) The cis isomer has stronger dipole-dipole forces; the trans isomer is nonpolar. (b) The cis isomer boils at 60.3 °C and the trans isomer boils at 47.5 °C. **11.78** When a halogen is substituted for H in benzene, molar mass, polarizability and strength of dispersion forces increase; the order of increasing molar mass is the order of increasing boiling points for the first three compounds. C_6H_5OH experiences hydrogen bonding, the strongest force between neutral molecules, so it has the highest boiling point. **11.81** A plot of number of carbon atoms versus boiling point indicates that the boiling point of C_8H_{18} is approximately 130 °C. The more carbon atoms in the hydrocarbon, the longer the chain, the more polarizable the electron cloud, the higher the boiling point. **11.83** (a) Evaporation is an endothermic process. The heat required to vaporize sweat is absorbed from your body, helping to keep it cool. (b) The vacuum pump reduces the pressure of the atmosphere above the water until atmospheric pressure equals the vapor pressure of water and the water boils. Boiling is an endothermic process, and the temperature drops if the system is not able to absorb heat from the surroundings fast enough. As the temperature of the water decreases, the water freezes. **11.88** At low Antarctic temperatures, molecules in the liquid crystalline phase have less kinetic energy due to temperature, and the applied voltage may not be sufficient to overcome orienting forces among the ends of molecules. If some or all of the molecules do not rotate when the voltage is applied, the display will not function properly.

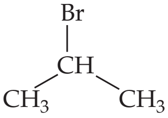
11.92



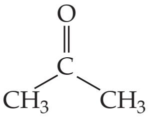
(i) $\mathbf{M} = 44$



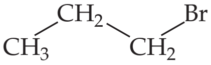
(ii) $\mathbf{M} = 72$



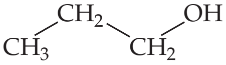
(iii) $\mathbf{M} = 123$



(iv) $\mathbf{M} = 58$



(v) $\mathbf{M} = 123$



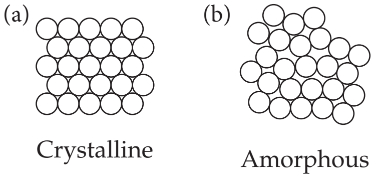
(vi) $\mathbf{M} = 60$

(a) Molar mass: Compounds (i) and (ii) have similar rodlike structures. The longer chain in (ii) leads to greater molar mass, stronger London dispersion forces, and higher heat of vaporization. (b) Molecular shape: Compounds (iii) and (v) have the same chemical formula and molar mass but different molecular shapes. The more rodlike shape of (v) leads to more contact between molecules, stronger dispersion forces, and higher heat of vaporization. (c) Molecular polarity: Compound (iv) has a smaller molar mass than (ii) but a larger heat of vaporization, which must be due to the presence of dipole–dipole forces. (d) Hydrogen bonding interactions: Molecules (v) and (vi) have similar structures. Even though (v) has larger molar mass and dispersion forces, hydrogen bonding causes (vi) to have the higher heat of vaporization. **11.96** $P(\text{benzene vapor}) = 98.7$ torr

Chapter 12

12.1 The orange compound is more likely to be a semiconductor and the white one an insulator. The orange compound absorbs light in the visible spectrum (orange is reflected, so blue is absorbed), while the white compound does not. This indicates that the orange compound has a lower energy electron transition than the white one. Semiconductors have lower energy electron transitions than insulators. **12.3** (a) The structure is hexagonal close-packed. (b) The coordination number, CN, is twelve. (c) CN(1) = 9, CN(2) = 6. **12.5** Fragment (b) is more likely to give rise to electrical conductivity. Arrangement (b) has a delocalized π system, in which electrons are free to move. Mobile electrons are required for electrical conductivity. **12.7** We expect linear polymer (a), with ordered regions, to be more crystalline and to have a higher melting point than branched polymer (b). **12.9** Statement (b) **12.11** (a) Hydrogen bonding, dipole-dipole forces, London dispersion forces (b) covalent chemical bonds (c) ionic bonds (d) metallic bonds **12.13** (a) Ionic (b) metallic (c) covalent-network (It could also be characterized as ionic with some covalent character to the bonds.) (d) molecular (e) molecular (f) molecular **12.15** Because of its relatively high melting point and properties as a conducting solution, the solid must be ionic.

12.17



12.19

Two-dimensional structure	(i)	(ii)
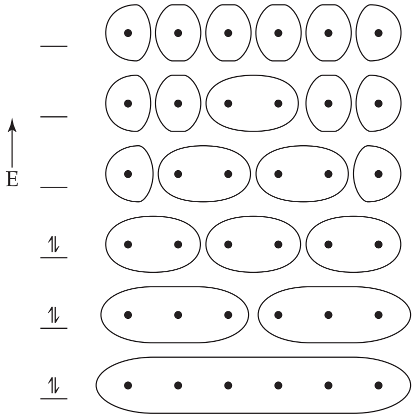
(a) unit cell		(b) γ, a, b	$\lambda = 90°, a = b$	$\lambda = 120°, a = b$
(c) lattice type	square	hexagonal

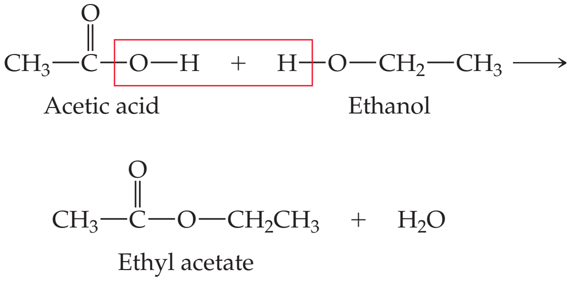
12.21 (a) Tetragonal **12.23** (e) Triclinic and rhombohedral **12.25** (b) 2 **12.27** (a) Primitive hexagonal unit cell (b) NiAs **12.29** Potassium. A body-centered cubic structure has more empty space than a face-centered cubic one. The more empty space, the less dense the solid. We expect the element with the lowest density, potassium, to adopt the body-centered cubic structure. **12.29** (a) Structure types A and C have equally dense packing and are more densely packed than structure type B. (b) Structure type B is least densely packed. **12.33** (a) The radius of an Ir atom is 1.355 Å. (b) The density of Ir is $22.67\ g/cm^3$ **12.35** (a) 4 Al atoms per unit cell (b) coordination number = 12 (c) $a = 4.04$ Å or 4.04×10^{-8} cm (d) density $= 2.71\ g/cm^3$ **12.35** An *alloy* contains atoms of more than one element and has the properties of a metal. In a *solution alloy* the components are randomly dispersed. In a *heterogeneous alloy* the components are not evenly dispersed and can be distinguished at a macroscopic level. In an *intermetallic compound* the components have interacted to form a compound substance, as in Cu_3As **12.39** Statement (b) is false. **12.41** (a) True (b) false (c) false **12.43** (a) Nickel or palladium, substitutional alloy (b) copper, substitutional alloy (c) silver, substitutional alloy **12.45** (a) True (b) false (c) false (d) false

12.47



(a) Six AOs require six MOs (b) zero nodes in the lowest energy orbital (c) five nodes in highest energy orbital (d) two nodes in the HOMO (e) three nodes in the LUMO (f) The HOMO-LUMO energy gap for the six-atom diagram is smaller than the one for the four-atom diagram. In general, the more atoms in the chain, the smaller the HOMO-LUMO energy gap. **12.49** (a) Ag is more ductile. Mo has stronger metallic bonding, a stiffer lattice, and is less susceptible to distortion. (b) Zn is more ductile. Si is a covalent-network solid with a stiffer lattice than metallic Zn. **12.51** Moving from Y to Mo, the number of valence electrons, occupancy of the bonding band, and strength of metallic bonding increase. Stronger metallic bonding requires more energy to break bonds and mobilize atoms, resulting in higher melting points. **12.53** (a) $SrTiO_3$ (b) Six (c) Each Sr atom is coordinated to a total of twelve O atoms in the eight unit cells that contain the Sr atom. **12.55** (a) $a = 4.70$ Å (b) 2.69 g/cm^3 **12.57** (a) 7.711 g/cm^3 (b) We expect Se^{2-} to have a larger ionic radius than S^{2-}, so HgSe will occupy a larger volume and the unit cell edge will be longer. (c) The density of HgSe is 8.241 g/cm^3. The greater mass of Se accounts for the greater density of HgSe. **12.59** (a) Cs^+ and I^- have the most similar radii and will adopt the CsCl-type structure. The radii of Na^+ and I^- are somewhat different; NaI will adopt the NaCl-type structure. The radii of Cu^+ and I^- are very different; CuI has the ZnS-type structure. (b) CsI, 8; NaI, 6; CuI, 4 **12.61** (a) 6 (b) 3 (c) 6 **12.63** (a) False (b) true **12.65** (a) Ionic solids are much more likely to dissolve in water. (b) Covalent-network solids can become electrical conductors via chemical substitution. **12.67** (a) CdS (b) GaN (c) GaAs **12.69** Ge or Si (Ge is closer to Ga in bonding atomic radius.) **12.71** (a) A 1.1 eV photon corresponds to a wavelength of 1.1×10^{-6} m (b) According to the figure, Si can absorb all wavelengths in the visible portion of the solar spectrum. (c) Si absorbs wavelengths less than 1,100 nm. This corresponds to approximately 80–90% of the total area under the curve. **12.73** The emitted light has a wavelength of 560 nm; its color is yellow-green. **12.75** The band gap is approximately 1.85 eV, which corresponds to a wavelength of 672 nm. **12.77** (a) A monomer is a small molecule with low molecular mass that can be joined together to form a polymer. They are the repeating units of a polymer. (b) ethene (also known as ethylene) **12.79** Reasonable values for a polymer's molecular weight are 10,000 amu, 100,000 amu, and 1,000,000 amu.

12.81



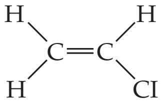
$$CH_3-\overset{\overset{\displaystyle O}{\|}}{C}\boxed{-O-H \quad + \quad H-}O-CH_2-CH_3 \longrightarrow$$

$$CH_3-\overset{\overset{\displaystyle O}{\|}}{C}-O-CH_2CH_3 \quad + \quad H_2O$$

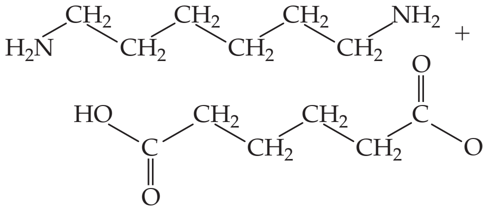
If a dicarboxylic acid and a dialcohol are combined, there is the potential for propagation of the polymer chain at both ends of both monomers.

12.83

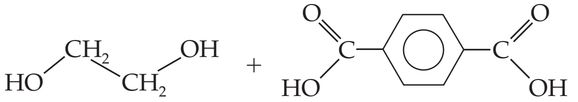
(a)



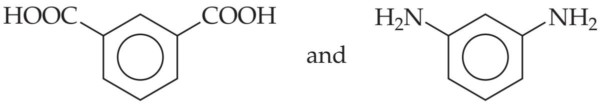
(b)



(c)



12.85



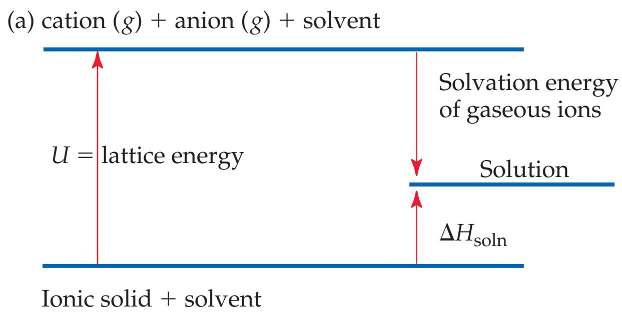
12.87 (a) Flexibility of the molecular chains causes flexibility of the bulk polymer. Flexibility is enhanced by molecular features that inhibit order, such as branching, and diminished by features that encourage order, such as cross-linking or delocalized π electron density. (b) Less flexible **12.89** Low degree of crystallinity **12.91** If a solid has nanoscale dimensions of 1–10 nm, there may not be enough atoms contributing atomic orbitals to produce continuous energy bands of molecular orbitals. **12.93** (a) False. As particle size decreases, the band gap increases. (b) False. As particle size decreases, wavelength decreases. **12.95** 2.47×10^5 Au atoms **12.97** Statement (b) is correct. **12.103** 3 Ni atoms, 1 Al atom; 6 Nb atoms, 2 Sn atoms; 1 Sm atom, 5 Co atoms. In each case, the atom ratio matches the empirical formula given in the exercise. **12.105** (a) White tin is a metal, while gray tin is a semiconductor. Delocalized electrons in the close-packed structure of white tin lead to metallic properties, while gray tin has the covalent-network structure characteristic of other Group IV semiconductors. (b) Metallic white tin has the longer bond distance because the valence electrons are shared with twelve nearest neighbors rather than being localized in four bonds as in gray tin. **12.107** (a) Zinc sulfide, ZnS (b) Covalent (c) In the solid, each Si is bound to four C atoms in a tetrahedral arrangement, and each C is bound to four Si atoms in a tetrahedral arrangement, producing an extended three-dimensional network. SiC is high-melting because melting requires breaking covalent Si—C bonds, which takes a huge amount of thermal energy. It is hard because the three-dimensional lattice resists any deformation that would weaken the Si—C bonding network. **12.113** The distance between planes in crystalline silicon is 3.13 Å. **12.119** (a) 109° (b) 120° (c) atomic *p* orbitals **12.123** (a) 2.50×10^{22} Si atoms (To 1 sig fig, the result is 2×10^{22} Si atoms.) (b) 1.29×10^{-3} mg P (1.29 μg P) **12.125** 99 Si atoms

Chapter 13

13.1 (a) < (b) < (c) **13.3** (a) No (b) The ionic solid with the smaller lattice energy will be more soluble in water. **13.7** Vitamin B_6 is more water soluble because of its small size and capacity for extensive hydrogen-bonding interactions. Vitamin E is more fat soluble. The long, rodlike hydrocarbon chain will lead to strong dispersion forces among vitamin E and mostly nonpolar fats. **13.9** (a) Yes, the *molarity* changes with a change in temperature. Molarity is defined as moles solute per unit volume of solution. A change of temperature changes solution volume and molarity. (b) No, *molality* does not change with change in temperature. Molality is defined as moles solute per kilogram of solvent. Temperature affects neither mass nor moles.

13.11 The volume inside the balloon will be 0.5 L, assuming perfect osmosis across the semipermeable membrane. **13.13** (a) False (b) false (c) true **13.15** (a) Dispersion (b) hydrogen bonding (c) ion–dipole (d) dipole–dipole **13.17** Very soluble. (b) ΔH_{mix} will be the largest negative number. In order for ΔH_{soln} to be negative, the magnitude of ΔH_{mix} must be greater than the magnitude of $(\Delta H_{solute} + \Delta H_{solvent})$. **13.19** (a) ΔH_{solute} (b) ΔH_{mix} **13.21** (a) ΔH_{soln} is nearly zero. Since the solute and solvent experience very similar London dispersion forces, the energy required to separate them individually and the energy released when they are mixed are approximately equal. $\Delta H_{solute} + \Delta H_{solvent} \approx -\Delta H_{mix}$. (b) The entropy of the system increases when heptane and hexane form a solution. From part (a), the enthalpy of mixing is nearly zero, so the increase in entropy is the driving force for mixing in all proportions. **13.23** (a) Supersaturated (b) Add a seed crystal. A seed crystal provides a nucleus of prealigned molecules, so that ordering of the dissolved particles (crystallization) is more facile. **13.25** (a) Unsaturated (b) saturated (c) saturated (d) unsaturated **13.27** (a) We expect the liquids water and glycerol to be miscible in all proportions. The —OH groups of glycerol facilitate strong hydrogen bonding similar to that in water; like dissolves like. (b) Hydrogen bonding, dipole-dipole forces, London dispersion forces **13.29** Toluene, $C_6H_5CH_3$, is the best solvent for nonpolar solutes. Without polar groups or nonbonding electron pairs, it forms only dispersion interactions with itself and other molecules. **13.31** (a) Dispersion interactions among nonpolar $CH_3(CH_2)_{16}$ — chains dominate the properties of stearic acid, causing it to be more soluble in nonpolar CCl_4 (b) Dioxane can act as a hydrogen bond acceptor, so it will be more soluble than cyclohexane in water. **13.33** (a) CCl_4 is more soluble because dispersion forces among nonpolar CCl_4 molecules are similar to dispersion forces in hexane. (b) C_6H_6 is a nonpolar hydrocarbon and will be more soluble in the similarly nonpolar hexane. (c) The long, rodlike hydrocarbon chain of octanoic acid forms strong dispersion interactions and causes it to be more soluble in hexane. **13.35** (a) A sealed container is required to maintain a partial pressure of $CO_2(g)$ greater than 1 atm above the beverage. (b) Since the solubility of gases increases with decreasing temperature, more $CO_2(g)$ will remain dissolved in the beverage if it is kept cool. **13.37** $S_{He} = 5.6 \times 10^{-4}\ M$, $S_{N_2} = 9.0 \times 10^{-4}\ M$ **13.39** (a) 2.15% Na_2SO_4 by mass (b) 3.15 ppm Ag **13.41** (a) $X_{CH_3OH} = 0.0427$ (b) 7.35% CH_3OH by mass (c) 2.48 m CH_3OH **13.43** (a) $1.46 \times 10^{-2}\ M$ $Mg(NO_3)_2$ (b) 1.12 M $LiClO_4 \cdot 3H_2O$ (c) 0.350 M HNO_3 **13.45** (a) 4.70 m C_6H_6 (b) 0.235 m NaCl **13.47** (a) 43.01% H_2SO_4 by mass (b) $X_{H_2SO_4} = 0.122$ (c) 7.69 m H_2SO_4 (d) 5.827 M H_2SO_4 **13.49** (a) $X_{CH_3OH} = 0.227$ (b) 7.16 m CH_3OH (c) 4.58 M CH_3OH **13.51** (a) 0.150 mol $SrBr_2$ (b) 1.56×10^{-2} mol KCl (c) 4.44×10^{-2} mol $C_6H_{12}O_6$ **13.53** (a) Weigh out 1.3 g KBr, dissolve in water, dilute with stirring to 0.75 L. (b) Weigh out 2.62 g KBr, dissolve it in 122.38 g H_2O to make exactly 125 g of 0.180 m solution. (c) Dissolve 244 g KBr in water, dilute with stirring to 1.85 L. (d) Weigh 10.1 g KBr, dissolve it in a small amount of water, and dilute to 0.568 L. **13.55** 71% HNO_3 by mass **13.57** (a) 3.82 m Zn (b) 26.8 M Zn **13.59** (a) 0.046 atm (b) $1.8 \times 10^{-3}\ M$ CO_2 **13.61** F (a) False (b) true (c) true (d) false **13.63** The vapor pressure of both solutions is 17.5 torr. Because these two solutions are so dilute, they have essentially the same vapor pressure. Generally, the less concentrated solution, the one with fewer moles of solute per kilogram of solvent, will have the higher vapor pressure. **13.65** (a) $P_{H_2O} = 186.4$ torr (b) 78.9 g $C_3H_8O_2$ **13.67** (a) $X_{Eth} = 0.2812$ (b) $P_{soln} = 238$ torr (c) X_{Eth} in vapor = 0.472 **13.69** (a) Because NaCl is a strong electrolyte, one mole of NaCl produces twice as many dissolved particles as one mole of the molecular solute $C_6H_{12}O_6$. Boiling-point elevation is directly related to total moles of dissolved particles, The 0.10 m NaCl has more dissolved particles so its boiling point is higher than the 0.10 m $C_6H_{12}O_6$. (b) In solutions of strong electrolytes like NaCl, ion pairing reduces the effective number of particles in solution, decreasing the change in boiling point. The actual boiling point is then lower than the calculated boiling point for a 0.10 m solution. **13.71** 0.050 m LiBr < 0.120 m glucose < 0.050 m $Zn(NO_3)_2$ **13.73** (a) $T_f = -115.0$ °C, $T_b = 78.7$ °C (b) $T_f = -67.3$ °C, $T_b = 64.2$ °C (c) $T_f = -0.4$ °C, $T_b = 100.1$ °C (d) $T_f = -0.6$ °C, $T_b = 100.2$ °C **13.75** 167 g $C_2H_6O_2$ **13.77** $\Pi = 0.0168$ atm = 12.7 torr **13.79** The approximate molar mass of adrenaline is 1.8×10^2 g. **13.81** Molar mass of lysozyme $= 1.39 \times 10^4$ g **13.83** (a) $i = 2.8$ (b) The more concentrated the solution, the greater the ion pairing and the smaller the measured value of *i*. **13.85** (a) No. In the gaseous state, particles are far apart and intermolecular attractive forces are small. When two gases combine, all terms in Equation 13.1 are essentially zero and the mixture is always homogeneous. (b) To determine whether Faraday's dispersion is a true solution or a colloid, shine a beam of light on it. If light is scattered, the dispersion is a colloid. **13.87** Choice (d), $CH_3(CH_2)_{11}$ COONa, is the best emulsifying agent. The long hydrocarbon chain will interact with the hydrophobic component, while the ionic end will interact with the hydrophilic component, as well as stabilize the colloid. **13.89** (a) No. The hydrophobic or hydrophilic nature of the protein will determine which electrolyte at which concentration will be the most effective precipitating agent. (b) Stronger. If a protein has been "salted out", protein-protein interactions are stronger than protein-solvent interactions and solid protein forms. (c) The first hypothesis seems plausible, since ion-dipole interactions among electrolytes and water molecules are stronger than dipole-dipole and hydrogen bonding interactions between water and protein molecules. But, we also know that ions adsorb on the surface of a hydrophobic colloid; the second hypothesis also seems plausible. If we could measure the charge and adsorbed water content of protein molecules as a function of salt concentration, then we could distinguish between these two hypotheses. **13.91** The periphery of the BHT molecule is mostly hydrocarbon-like groups, such as —CH_3. The one —OH group is rather buried inside and probably does little to enhance solubility in water. Thus, BHT is more likely to be soluble in the nonpolar hydrocarbon hexane, C_6H_{14}, than in polar water. **13.94** (a) $k_{Rn} = 7.27 \times 10^{-3}$ mol/L-atm (b) $P_{Rn} = 1.1 \times 10^{-4}$ atm; $S_{Rn} = 8.1 \times 10^{-7}\ M$ **13.98** (a) 2.69 m LiBr (b) $X_{LiBr} = 0.0994$ (c) 81.1% LiBr by mass **13.100** $X_{H_2O} = 0.808$; 0.0273 mol ions; 0.0136 mol NaCl; 0.798 g NaCl **13.103** (a) −0.6 °C (b) −0.4 °C **13.106** (a), CF_4, $1.7 \times 10^{-4}\ m$; $CClF_3$, $9 \times 10^{-4}\ m$; CCl_2F_2, $2.3 \times 10^{-2}\ m$; $CHClF_2$, $3.5 \times 10^{-2}\ m$ (b) Molality and molarity are numerically similar when kilograms solvent and liters solution are nearly equal. This is true when solutions are dilute and when the density of the solvent is nearly 1g/mL, as in this exercise. (c) Water is a polar solvent; the solubility of solutes increases as their polarity increases. Nonpolar CF_4 has the lowest solubility and the most polar fluorocarbon, $CHClF_2$, has the greatest solubility in H_2O. (d) The Henry's law constant for $CHClF_2$ is 3.5×10^{-2} mol/L-atm. This value is greater than the Henry's law constant for $N_2(g)$ because $N_2(g)$ is nonpolar and of lower molecular mass than $CHClF_2$.

13.109



(a) cation (g) + anion (g) + solvent
Solvation energy of gaseous ions
U = lattice energy
Solution
ΔH_{soln}
Ionic solid + solvent

(b) Lattice energy (U) is inversely related to the distance between ions, so salts with large cations like $(CH_3)_4N^+$ have smaller lattice energies than salts with simple cations like Na^+. Also the —CH_3 groups in the large cation are capable of dispersion interactions with nonpolar groups of the solvent molecules, resulting in a more negative solvation energy of the gaseous ions. Overall, for salts with larger cations, lattice energy is smaller (less positive), the solvation energy of the gaseous ions is more negative, and ΔH_{soln} is less endothermic. These salts are more soluble in polar nonaqueous solvents. **13.113** (a) $P_t = 330$ torr (b) Weak hydrogen bonds between the two molecules prevent molecules from escaping to the vapor phase and result in a lower than ideal vapor pressure for the solution. There is no hydrogen bonding in the pure liquids. (c) Exothermic. According to Coulomb's law, electrostatic attractive forces lead to an overall lowering of the energy of the system. $\Delta H_{soln} < 0$. (d) No. Chloromethane has only one chlorine atom withdrawing electron density from the central carbon atom, the three C—H bonds are less polarized, and interactions with acetone are weaker. There is probably some vapor pressure lowering, but much less than for chloroform and acetone.

Chapter 14

14.1 The rate of the combustion reaction in the cylinder depends on the surface area of the droplets in the spray. The smaller the droplets, the greater the surface area exposed to oxygen, the faster the combustion reaction. In the case of a clogged injector, larger droplets lead to slower combustion. Uneven combustion in the various cylinders can cause the engine to run roughly and decrease fuel economy. **14.3** Equation (iv) (b) rate $= -\Delta[B]/\Delta t = ½\Delta[A]/\Delta t$ **14.9** (1) Total potential energy of the reactants (2) E_a, activation energy of the reaction (3) ΔE, net energy change for the reaction (4) total potential energy of the products **14.12** (a) $NO_2 + F_2 \longrightarrow NO_2F + F$; $NO_2 + F \longrightarrow NO_2F$ (b) $2NO_2 + F_2 \longrightarrow 2NO_2F$ (c) F (atomic fluorine) is the intermediate (d) rate $= k[NO_2][F_2]$ **14.15** (a) Net reaction: $AB + AC \longrightarrow BA_2 + C$ (b) A is the intermediate. (c) A_2 is the catalyst. **14.17** (a) *Reaction rate* is the change in the amount of products or reactants in a given amount of time. (b) Rates depend on concentration of reactants, surface area of reactants, temperature, and presence of catalyst. (c) No. The stoichiometry of the reaction (mole ratios of reactants and products) must be known to relate rate of disappearance of reactants to rate of appearance of products.

14.19

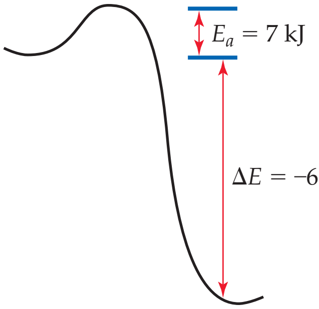
Time (min)	Mol A	(a) Mol B	[A] (mol/L)	Δ[A] (mol/L)	(b) Rate (M/s)
0	0.065	0.000	0.65		
10	0.051	0.014	0.51	−0.14	2.3×10^{-4}
20	0.042	0.023	0.42	−0.09	1.5×10^{-4}
30	0.036	0.029	0.36	−0.06	1.0×10^{-4}
40	0.031	0.034	0.31	−0.05	0.8×10^{-4}

(c) $\Delta[B]_{avg}/\Delta t = 1.3 \times 10^{-4}\ M/s$

14.21 (a)

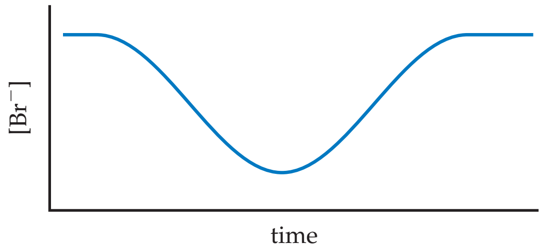
Time (s)	Time Interval (*s*)	Concentration (*M*)	Δ*M*	Rate (M/s)
0		0.0165		
2,000	2,000	0.0110	−0.0055	28×10^{-7}
5,000	3,000	0.00591	−0.0051	17×10^{-7}
8,000	3,000	0.00314	−0.00277	9.3×10^{-7}
12,000	4,000	0.00137	−0.00177	4.43×10^{-7}
15,000	3,000	0.00074	−0.00063	2.1×10^{-7}

(b) The average rate of reaction is $1.05 \times 10^{-6}\ M/s$ (c) The average rate between $t = 2{,}000$ and $t = 12{,}000$ s ($9.63 \times 10^{-7}\ M/s$) is greater than the average rate between $t = 8{,}000$ and $t = 15{,}000$ s ($3.43 \times 10^{-7}\ M/s$). (d) From the slopes of the tangents to the graph, the rates are $12 \times 10^{-7}\ M/s$ at 5000 s, $5.8 \times 10^{-7}\ M/s$ at 8000 s. **14.23** (a) $-\Delta[H_2O_2]/\Delta t = \Delta[H_2]/\Delta t = \Delta[O_2]/\Delta t$ (b) $-\frac{1}{2}\Delta[N_2O]/\Delta t = \frac{1}{2}\Delta[N_2]/\Delta t = \Delta[O_2]/\Delta t$ (c) $-\Delta[N_2]/\Delta t = -1/3\Delta[H_2]/\Delta t = -1/2\Delta[NH_3]/\Delta t$ (d) $-\Delta[C_2H_5NH_2]/\Delta t = \Delta[C_2H_4]/\Delta t = \Delta[NH_3]/\Delta t$ **14.25** (a) $-\Delta[O_2]/\Delta t = 0.24$ mol/s; $\Delta[H_2O]/\Delta t = 0.48$ mol/s (b) P_{total} decreases by 28 torr/min . **14.27** (a) If [A] doubles, there is no change in the rate or the rate constant. (b) The reaction is zero order in A, second order in B, and second order overall. (c) units of $k = M^{-1}s^{-1}$ **14.29** (a) Rate $= k[N_2O_5]$ (b) Rate $= 1.16 \times 10^{-4}\ M/s$ (c) When the concentration of N_2O_5 doubles, the rate doubles. (d) When the concentration of N_2O_5 is halved, the rate doubles. **14.31** (a, b) $k = 1.7 \times 10^2\ M^{-1}s^{-1}$ (c) If $[OH^-]$ is tripled, the rate triples. (d) If $[OH^-]$ and $[CH_3Br]$ both triple, the rate increases by a factor of 9. **14.33** (a) Rate $= k[OCl^-][I^-]$ (b) $k = 60\ M^{-1}s^{-1}$. (c) Rate $= 6.0 \times 10^{-5}\ M/s$ **14.35** (a) Rate $= k[BF_3][NH_3]$ (b) The reaction is second order overall. (c) $k_{avg} = 3.41\ M^{-1}s^{-1}$ (d) $0.170\ M/s$ **14.37** (a) Rate $= k[NO]^2[Br_2]$ (b) $k_{avg} = 1.2 \times 10^4\ M^{-2}s^{-1}$ (c) $\frac{1}{2}\Delta[NOBr]/\Delta t = -\Delta[Br_2]/\Delta t$ (d) $-\Delta[Br_2]/\Delta t = 8.4\ M/s$ **14.39** (a) $[A]_0$ is the molar concentration of reactant A at time zero. $[A]_t$ is the molar concentration of reactant A at time *t*. $t_{1/2}$ is the time required to reduce $[A]_0$ by a factor of 2. *k* is the rate constant for a particular reaction. (b) A graph of ln[A] versus time yields a straight line for a first-order reaction. (c) On a graph of ln[A] versus time, the rate constant is the (–slope) of the straight line. **14.41** (a) $k = 3.0 \times 10^{-6} s^{-1}$ (b) $t_{1/2} = 3.2 \times 10^4$ s **14.43** (a) $P = 30$ torr (b) $t = 51$ s **14.45** Plot $(\ln P_{SO_2Cl_2})$ versus time, $k = -\text{slope} = 2.19 \times 10^{-5}s^{-1}$ **14.47** (a) The plot of $1/[A]$ versus time is linear, so the reaction is second order in [A]. (b) $k = 0.040\ M^{-1}\ \text{min}^{-1}$ (c) $t_{1/2} = 38$ min **14.49** (a) The plot of $1/[NO_2]$ versus time is linear, so the reaction is second order in NO_2. (b) $k = \text{slope} = 10\ M^{-1}s^{-1}$ (c) rate at $0.200\ M = 0.400\ M/s$, rate at $0.100\ M = 0.100\ M/s$; rate at $0.050\ M = 0.025\ M/s$ **14.51** (a) The energy of the collision and the orientation of the molecules when they collide determine whether a reaction will occur. (b) At a higher temperature, there are more total collisions and each collision is more energetic. (c) The rate constant usually increases with an increase in reaction temperature. **14.53** $f = 4.94 \times 10^{-2}$. At 400 K, approximately 1 out of 20 molecules has this kinetic energy. **14.55** (a)



(b) E_a(reverse) $= 73$ kJ **14.57** (a) False (b) false (c) true **14.59** Reaction (b) is fastest and reaction (c) is slowest. **14.61** (a) $k = 1.1\ s^{-1}$ (b) $k = 13\ s^{-1}$ (c) The method in parts (a) and (b) assumes that the collision model and thus the Arrhenious equation describe the kinetics of the reactions. That is, activation energy is constant over the temperature range under consideration. **14.63** A plot of ln *k* versus $1/T$ has a slope of -5.71×10^3; $E_a = -R(\text{slope}) = 47.5$ kJ/mol. **14.65** (a) An *elementary reaction* is a process that occurs as a single event; the order is given by the coefficients in the balanced equation for the reaction. (b) A *unimolecular* elementary reaction involves only one reactant molecule; a *bimolecular* elementary reaction involves two reactant molecules. (c) A *reaction mechanism* is a series of elementary reactions that describes how an overall reaction occurs and explains the experimentally determined rate law. (d) A *rate-determining step* is the slow step in a reaction mechanism. It limits the overall reaction rate. **14.67** (a) Unimolecular, rate $= k[Cl_2]$ (b) bimolecular, rate $= k[OCl^{-1}][H_2O]$ (c) bimolecular, rate $= k[NO][Cl_2]$ **14.69** (a) Two intermediates, B and C. (b) three transition states (c) $C \longrightarrow D$ is fastest. (d) ΔE is positive. **14.71** (a) $H_2(g) + 2ICI(g) \longrightarrow I_2(g) + 2HCl(g)$ (b) HI is the intermediate. (c) If the first step is slow, the observed rate law is rate = $k[H_2][ICl]$. **14.73** (a) The two-step mechanism is consistent with the data, assuming that the second step is rate determining. (b) No. The linear plot guarantees that the overall rate law will include $[NO]^2$. Since the data were obtained at constant $[Cl_2]$, we have no information about reaction order with respect to $[Cl_2]$. **14.75** (a) A catalyst is a substance that changes (usually increases) the speed of a chemical reaction without undergoing a permanent chemical change itself. (b) A homogeneous catalyst is in the same phase as the reactants, while a hetereogeneous catalyst is in a different phase. (c) A catalyst has no effect on the overall enthalpy change for a reaction, but it does affect activation energy. It can also affect the frequency factor.

14.77



14.79 (a) Multiply the coefficients in the first reaction by 2 and sum. (b) $NO_2(g)$ is a catalyst. (c) This is a homogeneous catalysis. **14.81** (a) Use of chemically stable supports makes it possible to obtain very large surface areas per unit mass of the precious metal catalyst because the metal can be deposited in a very thin, even monomolecular, layer on the surface of the support. (b) The greater the surface area of the catalyst, the more reaction sites, the greater the rate of the catalyzed reaction. **14.83** To put two D atoms on a single carbon, it is necessary that one of the already existing C—H bonds in ethylene be broken while the molecule is adsorbed, so that the H atom moves off as an adsorbed atom and is replaced by a D atom. This requires a larger activation energy than simply adsorbing C_2H_4 and adding one D atom to each carbon. **14.85** Carbonic anhydrase lowers the activation energy of the reaction by 42 kJ. **14.87** (a) The catalyzed reaction is approximately 10,000,000 times faster at 25 °C (b) The catalyzed reaction is 180,000 times faster at 125 °C. **14.91** (a) Rate $= 4.7 \times 10^{-5}\ M/s$ (b, c) $k = 0.84\ M^{-2}s^{-1}$ (d) If the [NO] is increased by a factor of 1.8, the rate would increase by a factor of 3.2. **14.95** (a) The reaction is second order in NO_2. (b) If $[NO_2]_0 = 0.100\ M$ and $[NO_2]_t = 0.025\ M$, use the integrated form of the second-order rate equation to solve for t. $t = 48$ s **14.99** (a) The half-life of ^{241}Am is 4.3×10^2 yr, that of ^{125}I is 63 days (b) ^{125}I decays at a much faster rate. (c) 0.13 mg of each isotope remains after 3 half-lives. (d) The amount of ^{241}Am remaining after 4 days is 1.00 mg. The amount of ^{125}I remaining after 4 days is 0.96 mg. **14.103** (a) The plot of $1/[C_5H_6]$ versus time is linear and the reaction is second order. (b) $k = 0.167\ M^{-1}\ s^{-1}$ **14.107** (a) When the two elementary reactions are added, $N_2O_2(g)$ appears on both sides and cancels, resulting in the overall reaction. $2NO(g) + H_2(g) \longrightarrow N_2O(g) + H_2O(g)$ (b) First reaction, $-[NO]/\Delta t = k[NO]^2$, second reaction, $-[H_2]/\Delta t = k[H_2][N_2O_2]$ (c) N_2O_2 is the intermediate. (d) Because $[H_2]$ appears in the rate law, the second step must be slow relative to the first. **14.110** (a) $Cl_2(g) + CHCl_3(g) \longrightarrow HCl(g) + CCl_4(g)$ (b) $Cl(g)$, $CCl_3(g)$ (c) reaction 1, unimolecular; reaction 2, bimolecular; reaction 3, bimolecular (d) Reaction 2 is rate determining. (e) Rate $= k[CHCl_3][Cl_2]^{1/2}$. **14.115** The enzyme must lower the activation energy by 22 kJ in order to make it useful.

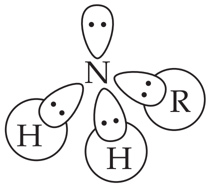
14.120 (a) $k = 8 \times 10^7\ M^{-1}s^{-1}$

(b) 

(c) NOF is bent with a bond angle of approximately 120°

(d) 
(e) The electron-deficient NO molecule is attracted to electron-rich F_2 so the driving force for formation of the transition state is greater than simple random collisions.

14.123 (a)



(b) A reactant that is attracted to the lone pair of electrons on nitrogen will produce a tetrahedral intermediate. This can be a moiety with a full, partial or even transient positive charge.

Chapter 15

15.1 $k_f > k_r$ (b) The equilibrium constant is greater than one. **15.3** K is greater than one. **15.5** $A(g) + B(g) \rightleftharpoons AB(g)$ has the larger equilibrium constant. **15.6** From the smallest to the largest equilibrium constant, (c) < (b) < (a). **15.7** Statement (b) is true. **15.9** Two B atoms should be added to the diagram. **15.11** K_c decreases as T increases, so the reaction is exothermic. **15.13** (a) $K_p = K_c = 8.1 \times 10^{-3}$. (b) At equilibrium, the partial pressure of A is greater than the partial pressure of B. **15.15** (a) $K_c = [N_2O][NO_2]/[NO]^3$; homogeneous (b) $K_c = [CS_2][H_2]^4/[CH_4][H_2S]^2$; homogeneous (c) $K_c = [CO]^4/[Ni(CO)_4]$; heterogeneous (d) $K_c = [H^+][F^-]/[HF]$; homogeneous (e) $K_c = [Ag^+]^2/[Zn^{2+}]$; heterogeneous (f) $K_c = [H^+][OH^-]$; homogeneous (g) $K_c = [H^+]^2[OH^-]^2$; homogeneous **15.17** (a) Mostly reactants (b) mostly products **15.19** (a) True (b) false (c) false **15.21** $K_p = 1.0 \times 10^{-3}$ **15.23** (a) The equilibrium favors NO and Br_2 at this temperature. (b) $K_c = 77$ (c) $K_c = 8.8$ **15.25** (a) $K_p = 0.541$ (b) $K_p = 3.42$ (c) $K_c = 281$ **15.27** $K_c = 0.14$ **15.29** (a) $K_p = P_{O_2}$ (b) $K_c = [Hg(solv)]^4[O_2(solv)]$ **15.31** $K_c = 10.5$ **15.33** (a) $K_p = 51$ (b) $K_c = 2.1 \times 10^3$ **15.35** (a) $[H_2] = 0.012\ M$, $[N_2] = 0.019\ M$, $[H_2O] = 0.138\ M$ (b) $K_c = 653.7 = 7 \times 10^2$ **15.37** (a) $P_{CO_2} = 4.10$ atm, $P_{H_2} = 2.05$ atm, $P_{H_2O} = 3.28$ atm, (b) $P_{CO_2} = 3.87$ atm, $P_{H_2} = 1.82$ atm, $P_{CO} = 0.23$ atm (c) $K_p = 0.11$ (d) $K_c = 0.11$ **15.39** $K_c = 2.0 \times 10^4$ **15.41** (a) To the right (b) The concentrations used to calculate Q must be equilibrium concentrations. **15.45** (a) $Q = 1.1 \times 10^{-8}$, the reaction will proceed to the left. (b) $Q = 5.5 \times 10^{-12}$, the reaction will proceed to the right. (c) $Q = 2.19 \times 10^{-10}$, the mixture is at equilibrium. **15.45** $P_{Cl_2} = 5.0$ atm **15.47** $[Br_2] = 0.00767\ M$, $[Br] = 0.00282\ M$, 0.0451 g $Br(g)$ **15.49** $[I] = 2.10 \times 10^{-5}\ M$, $[I_2] = 1.43 \times 10^{-5}\ M$, 0.0362 g I_2 **15.51** $[NO] = 0.002\ M$, $[N_2] = [O_2] = 0.087\ M$ **15.53** The equilibrium pressure of $Br_2(g)$ is 0.416 atm. **15.55** (a) $[Ca^{2+}] = [SO_4^{2-}] = 4.9 \times 10^{-3}\ M$ (b) A bit more than 1.0 g $CaSO_4$ is needed in order to have some undissolved $CaSO_4(s)$ in equilibrium with 1.4 L of saturated solution. **15.57** $[IBr] = 0.223\ M$, $[I_2] = [Br_2] = 0.0133\ M$ **15.59** (a) $P_{CH_3I} = P_{HI} = 0.422$ torr, $P_{CH_4} = 104.7$ torr, $P_{I_2} =$ torr **15.61** (a) Shift equilibrium to the right (b) decrease the value of K (c) shift equilibrium to the left (d) no effect (e) no effect (f) shift equilibrium to the right **15.63** (a) No effect (b) no effect (c) no effect (d) increase equilibrium constant (e) no effect **15.65** (a) $\Delta H° = -155.7$ kJ (b) The reaction is exothermic, so the equilibrium constant will decrease with increasing temperature. (c) Δn does not equal zero, so a change in volume at constant temperature will affect the fraction of products in the equilibrium mixture. **15.67** An increase in pressure favors formation of ozone. **15.71** $K_p = 24.7$; $K_p = 24.7$; $K_c = 3.67 \times 10^{-3}$ **15.74** (a) $P_{Br_2} = 1.61$ atm, $P_{NO} = 0.628$ atm, $P_{NOBr} = 0.179$ atm; $K_c = 0.0643$ (b) $P_t = 0.968$ atm (c) 10.49 g NOBr **15.77** At equilibrium, $P_{IBr} = 0.21$ atm, $P_{I_2} = P_{Br_2} = 1.9 \times 10^{-3}$ atm **15.80** $K_p = 4.33$, $K_c = 0.0480$ **15.83** $[CO_2] = [H_2] = 0.264\ M$, $[CO] = [H_2O] = 0.236\ M$ **15.87** (a) 26% of the CCl_4 is converted to C and Cl_2. (b) $P_{CCl_4} =$

1.47 atm, $P_{Cl_2} = 1.06$ atm **15.91** $Q = 8 \times 10^{-6}$. $Q > K_p$, so the system is not at equilibrium; it will shift left to attain equilibrium. A catalyst that speeds up the reaction and thereby promotes the attainment of equilibrium would decrease the CO concentration in the exhaust. **15.93** At equilibrium, $[H_4IO_6^-] = 0.0015\ M$ **15.97** At 850 °C, $K_p = 14.1$; at 950 °C, $K_p = 73.8$; at 1050 °C, $K_p = 2.7 \times 10^2$; at 1200 °C, $K_p = 1.7 \times 10^3$. Because K increases with increasing temperature, the reaction is endothermic.

Chapter 16

16.1 (a) HCl, the H^+ donor, is the Brønsted–Lowry acid. NH_3, the H^+ acceptor, is the Brønsted–Lowry base. (b) HCl, the electron pair acceptor, is the Lewis acid. NH_3, the electron pair donor, is the Lewis base. **16.3** (a) True. (b) False. Methyl orange turns yellow at a pH slightly greater than 4, so solution B could be at any pH greater than 4. (c) True. **16.5** (a) HY is a strong acid. There are no neutral HY molecules in solution, only H^+ cations and Y^- anions. (b) HX has the smallest K_a value. It has most neutral acid molecules and fewest ions. (c) HX has fewest H^+ and highest pH. **16.7** (a) Curve C (b) For a weak acid, the percent ionization is inversely related to acid concentration; curve C depicts this relationship. It is the only curve that shows a decrease in percent ionization as acid concentration increases. **16.9** (a) Basic (b) Phenylephrine hydrochloride is a salt, while phenylephrine is a neutral molecule. The cation in the salt has an additional H atom bound to the N of phenylephrine. The anion is chloride. **16.11** (a) Molecule (b) is more acidic because its conjugate base is resonance-stabilized and the ionization equilibrium favors the more stable products. (b) Increasing the electronegativity of X increases the strength of both acids. As X becomes more electronegative and attracts more electron density, the O—H bond becomes weaker, more polar, and more likely to be ionized. An electronegative X group also stabilizes the anionic conjugate bases by delocalizing the negative charge. The equilibria favor products and the values of K_a increase. **16.13** (a) The Arrhenius definition of an acid is confined to aqueous solution; the Brønsted–Lowry definition applies to any physical state. (b) HCl is the Brønsted–Lowry acid; NH_3 is the Brønsted–Lowry base. **16.15** **(a)** (i) IO_3^- (ii) NH_3 **(b)** (i) OH^- (ii) H_3PO_4
16.17

Acid	+	Base	$\rightleftharpoons$	Conjugate Acid	+	Conjugate Base
(a) $NH_4^+(aq)$		$CN^-(aq)$		HCN(aq)		$NH_3(aq)$
(b) $H_2O(l)$		$(CH_3)_3N(aq)$		$(CH_3)_3NH^+(aq)$		$OH^-(aq)$
(c) HCOOH(aq)		$PO_4^{3-}(aq)$		$HPO_4^{2-}(aq)$		$HCOO^-(aq)$

16.19 (a) Acid: $HC_2O_4^-(aq) + H_2O(l) \rightleftharpoons C_2O_4^{2-}(aq) + H_3O^+(aq)$; Base: $HC_2O_4^-(aq) + H_2O(l) \rightleftharpoons H_2C_2O_4(aq) + OH^-(aq)$. (b) $H_2C_2O_4$ is the conjugate acid of $HC_2O_4^-$. $C_2O_4^{2-}$ is the conjugate base of $HC_2O_4^-$ **16.21** (a) CH_3COO^-, weak base; CH_3COOH, weak acid (b) HCO_3^-, weak base; H_2CO_3 weak acid (c) O_2^-, strong base; OH^-, strong base (d) Cl^-, negligible base; HCl, strong acid (e) NH_3, weak base; NH_4^+, weak acid **16.23** (a) HBr (b) F^- **16.25** (a) $OH^-(aq) + OH^-(aq)$, the equilibrium lies to the right. (b) $H_2S(aq) + CH_3COO^-(aq)$, the equilibrium lies to the right. (c) $HNO_3(aq) + OH^-(aq)$, the equilibrium lies to the left. **16.27** Statement (ii) is correct. **16.29** (a) $[H^+] = 2.2 \times 10^{-11}\ M$, basic (b) $[H^+] = 1.1 \times 10^{-6}\ M$, acidic (c) $[H^+] = 1.0 \times 10^{-8}\ M$, basic **16.31** $[H^+] = [OH^-] = 3.5 \times 10^{-8}\ M$ **16.33** (a) $[H^+]$ changes by a factor of 100. (b) $[H^+]$ changes by a factor of 3.2 **16.35**

$[H^+]$	$[OH^-]$	pH	pOH	Acidic or Basic
$7.5 \times 10^{-3}\ M$	$1.3 \times 10^{-12} M$	2.12	11.88	acidic
$2.8 \times 10^{-5}\ M$	$3.6 \times 10^{-10} M$	4.56	9.44	acidic
$5.6 \times 10^{-9}\ M$	$1.8 \times 10^{-6} M$	8.25	5.75	basic
$5.0 \times 10^{-9}\ M$	$2.0 \times 10^{-6} M$	8.30	5.70	basic

16.37 $[H^+] = 4.0 \times 10^{-8}\ M$, $[OH^-] = 6.0 \times 10^{-7}\ M$, pOH = 6.22
16.39 (a) Acidic (b) The range of possible integer pH values for the solution is 4-6. (c) Methyl violet, thymol blue, methyl orange and methyl red would help determine the pH of the solution more precisely.
16.41 (a) True (b) true (c) false
16.43 (a) $[H^+] = 8.5 \times 10^{-3}\ M$, pH = 2.07
(b) $[H^+] = 0.0419\ M$, pH = 1.377 (c) $[H^+] = 0.0250\ M$, pH = 1.602
(d) $[H^+] = 0.167\ M$, pH = 0.778
16.45 (a) $[OH^-] = 3.0 \times 10^{-3}\ M$, pH = 11.48
(b) $[OH^-] = 0.3758\ M$, pH = 13.5750
(c) $[OH^-] = 8.75 \times 10^{-5}\ M$, pH = 9.942
(d) $[OH^-] = 0.17\ M$, pH = 13.23 **16.47** $3.2 \times 10^{-3}\ M$ NaOH
16.49 (a) $HBrO_2(aq) \rightleftharpoons H^+(aq) + BrO_2^-(aq)$,
$K_a = [H^+][BrO_2^-]/[HBrO_2]$;
$HBrO_2(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + BrO_2^-(aq)$
$K_a = [H_3O^+][BrO_2^-]/[HBrO_2]$
(b) $C_2H_5COOH(aq) \rightleftharpoons H^+(aq) + C_2H_5COO^-(aq)$
$K_a = [H^+][C_2H_5COO^-]/[C_2H_5COOH]$; $C_2H_5COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + C_2H_5COO^-(aq)$
$K_a = [H_3O^+][C_2H_5COO^-]/[C_2H_5COOH]$ **16.51** $K_a = 1.4 \times 10^{-4}$
16.53 $[H^+] = [ClCH_2COO^-] = 0.0110\ M$, $[ClCH_2COOH] = 0.089\ M$, $K_a = 1.4 \times 10^{-3}$
16.55 0.089 M CH_3COOH
16.57 $[H^+] = [C_6H_5COO^-] = 1.8 \times 10^{-3}\ M$, $[C_6H_5COOH] = 0.048\ M$
16.59 (a) $[H^+] = 1.1 \times 10^{-3}\ M$, pH = 2.95
(b) $[H^+] = 1.7 \times 10^{-4}\ M$, pH = 3.76
(c) $[OH^-] = 1.4 \times 10^{-5}\ M$, pH = 9.15
16.61 $[H^+] = 2.0 \times 10^{-2}\ M$, pH = 1.71
16.63 (a) $[H^+] = 2.8 \times 10^{-3}\ M$, 0.69% ionization
(b) $[H^+] = 1.4 \times 10^{-3}\ M$, 1.4% ionization
(c) $[H^+] = 8.7 \times 10^{-4}\ M$, 2.2% ionization
16.65 (a) $[H^+] = 5.1 \times 10^{-3}\ M$, pH = 2.30. The approximation that the first ionization is less than 5% of the total acid concentration is not valid; the quadratic equation must be solved. The $[H^+]$ produced from the second and third ionizations is small with respect to that present from the first step; the second and third ionizations can be neglected when calculating the $[H^+]$ and pH. (c) $[C_6H_5O_7^{3-}]$ is much less than $[H^+]$. **16.67** (a) $HONH_3^+$ (b) When hydroxylamine acts as a base, the nitrogen atom accepts a proton. (c) In hydroxylamine, O and N are the atoms with nonbonding electron pairs; in the neutral molecule both have zero formal charges. Nitrogen is less electronegative than oxygen and more likely to share a lone pair of electrons with an incoming (and electron-deficient) H^+. The resulting cation with the +1 formal charge on N is more stable than the one with the +1 formal charge on O.
16.69 (a)
$(CH_3)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3)_2NH_2^+(aq) + OH^-(aq)$;
$K_b = [(CH_3)_2NH_2^+][OH^-]/[(CH_3)_2NH]$
(b) $CO_3^{2-}(aq) + H_2O(l) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$;
$K_b = [HCO_3^-][OH^-]/[(CO_3^{2-})]$
(c) $HCOO^-(aq) + H_2O(l) \rightleftharpoons HCOOH(aq) + OH^-(aq)$; $K_b = [HCOOH][OH^-]/[HCOO^-]$
16.71 From the quadratic formula, $[OH^-] = 6.6 \times 10^{-3}\ M$, pH = 11.82. **16.73** (a) $[C_{10}H_{15}ON] = 0.033\ M$, $[C_{10}H_{15}ONH^+] = [OH^+] = 2.1 \times 10^{-3}\ M$ (b) $K_b = 1.4 \times 10^{-4}$ **16.75** (a) For a conjugate acid/conjugate base pair such as $C_6H_5OH/C_6H_5O^-$, K_b for the conjugate base can always be calculated from K_a for the conjugate acid, so a separate list of K_b values is not necessary. (b) $K_b = 7.7 \times 10^{-5}$ (c) Phenolate is a stronger base than NH_3. **16.77** (a) Acetic acid is stronger. (b) Hypochlorite ion is the stronger base. (c) For CH_3COO^-, $K_b = 5.6 \times 10^{-10}$; for ClO^-, $K_b = 3.3 \times 10^{-7}$. **16.79** (a) $[OH^-] = 6.3 \times 10^{-4}\ M$, pH = 10.80 (b) $[OH^-] = 9.2 \times 10^{-5}\ M$, pH = 9.96
(c) $[OH^-] = 3.3 \times 10^{-6}\ M$, pH = 8.52 **16.81** 4.5 M $NaCH_3COO$
16.83 (a) Acidic (b) acidic (c) basic (d) neutral (e) acidic **16.85** K_b for the anion of the unknown salt is 1.4×10^{-11}; K_a for the conjugate acid is 7.1×10^{-4}. The conjugate acid is HF and the salt is NaF.
16.87 (a) HNO_3 is a stronger acid because it has one more nonprotonated oxygen atom and thus a higher oxidation number on N. (b) For binary hydrides, acid strength increases going down a family, so H_2S is a stronger acid than H_2O. (c) H_2SO_4 is a stronger acid because H^+

is much more tightly held by the anion HSO_4^-. (d) For oxyacids, the greater the electronegativity of the central atom, the stronger the acid, so H_2SO_4 is the stronger acid. (e) CCl_3COOH is stronger because the electronegative Cl atoms withdraw electron density from other parts of the molecule, which weakens the O—H bond and stabilizes the anionic conjugate base. Both effects favor increased ionization and acid strength. **16.89** (a) BrO^- (b) BrO^- (c) HPO_4^{2-} **16.91** (a) True (b) False. In a series of acids that have the same central atom, acid strength increases with the number of nonprotonated oxygen atoms bonded to the central atom. (c) False. H_2Te is a stronger acid than H_2S because the H—Te bond is longer, weaker, and more easily ionized than the H—S bond. **16.93** Yes. Any substance that fits the narrow Arrhenius definition will fit the broader Brønsted and Lewis definitions of a base. **16.95** (a) Acid, $Fe(ClO_4)_3$ or Fe^{3+}, base, H_2O (b) Acid, H_2O; base, CN^- (c) Acid, BF_3; base, $(CH_3)_3N$ (d) Acid, HIO; base, NH_2^- **16.97** (a) Cu^{2+}, higher cation charge (b) Fe^{3+}, higher cation charge (c) Al^{3+}, smaller cation radius, same charge **16.101** $K = 3.3 \times 10^7$ **16.106** pH = 7.01 (not 5.40, from the typical calculation, which does not make sense.) Usually we assume that $[H^+]$ and $[OH^-]$ from the autoionization of water do not contribute to the overall $[H^+]$ and $[OH^-]$. However, for acid or base solute concentrations less than $1 \times 10^{-6}\ M$, the autoionization of water produces significant $[H^+]$ and $[OH^-]$ and we must consider it when calculating pH. **16.109** (a) $pK_b = 9.16$ (b) pH = 3.07 (c) pH = 8.77 **16.113** Nicotine, protonated; caffeine, neutral base; strychnine, protonated; quinine, protonated **16.116** $6.0 \times 10^{13}\ H^+$ ions **16.119** (a) To the precision of the reported data, the pH of rainwater 40 years ago was 5.4, no different from the pH today. With extra significant figures, $[H^+] = 3.61 \times 10^{-6}\ M$, pH = 5.443 (b) A 20.0-L bucket of today's rainwater contains 0.02 L (with extra significant figures, 0.0200 L) of dissolved CO_2. **16.123** Rx 1, $\Delta H = 104$ kJ; Rx 2, $\Delta H = -32$ kJ. Reaction 2 is exothermic while reaction 1 is endothermic. For binary acids with heavy atoms (X) in the same family, the longer and weaker the H—X bond, the stronger the acid (and the more exothermic the ionization reaction). **16.126** (a) $K(\text{i}) = 5.6 \times 10^3$, $K(\text{ii}) = 10$ (b) Both (i) and (ii) have $K > 1$ so both could be written with a single arrow.

Chapter 17

17.1 The middle box has the highest pH. For equal amounts of acid HX, the greater the amount of conjugate base X^-, the smaller the amount of H^+ and the higher the pH. **17.7** (a) The red curve corresponds to the more concentrated acid solution. (b) On the titration curve of a weak acid, pH = pK_a at the volume halfway to the equivalence point. Reading the pK_a values from the two curves, the red curve has the smaller pK_a and the larger K_a. **17.09** (a) The right-most diagram represents the solubility of $BaCO_3$ as HNO_3 is added. (b) The left-most diagram represents the solubility of $BaCO_3$ as Na_2CO_3 is added. (c) The center diagram represents the solubility of $BaCO_3$ as $NaNO_3$ is added. **17.13** Statement (a) is most correct. **17.15** (a) $[H^+] = 1.8 \times 10^{-5} M$, pH = 4.73 (b) $[OH^-] = 4.8 \times 10^{-5} M$, pH = 9.68 (c) $[H^+] = 1.4 \times 10^{-5} M$, pH = 4.87 **17.17** (a) 4.5% ionization (b) 0.018% ionization **17.19** Only solution (a) is a buffer. **17.21** (a) pH = 3.82 (b) pH = 3.96 **17.23** (a) pH = 5.26
(b) $Na^+(aq) + CH_3COO^-(aq) + H^+(aq) + Cl^-(aq) \longrightarrow CH_3COOH(aq) + Na^+(aq) + Cl^-(aq)$
(c) $CH_3COOH(aq) + Na^+(aq) + OH^-(aq) \longrightarrow CH_3COO^-(aq) + H_2O(l) + Na^+(aq)$
17.25 (a) pH = 1.58 (b) 36 g NaF **17.27** (a) pH = 4.86 (b) pH = 5.0 (c) pH = 4.71 **17.29** (a) $[HCO_3^-]/[H_2CO_3] = 11$ (b) $[HCO_3^-]/[H_2CO_3] = 5.4$ **17.31** 360 mL of 0.10 *M* HCOONa, 640 mL of 0.10 *M* HCOOH **17.33** (a) Curve B (b) pH at the approximate equivalence point of curve A = 8.0, pH at the approximate equivalence point of curve B = 7.0 (c) For equal volumes of A and B, the concentration of acid B is greater, since it requires a larger volume of base to reach the equivalence point. (d) The pK_a value of the weak acid is approximately 4.5 **17.35** (a) False (b) true (c) true **17.37** (a) Above pH 7 (b) below pH 7 (c) at pH 7 **17.39** The second color change of thymol blue is in the correct pH range to show the equivalence point of the titration of a weak acid with a strong base. **17.41** (a) 42.4 mL NaOH soln (b) 35.0 mL NaOH soln (c) 29.8 mL NaOH soln **17.43** (a) pH = 1.54 (b) pH = 3.30 (c) pH = 7.00 (d) pH = 10.69 (e) pH = 12.74 **17.45** (a) pH = 2.78 (b) pH = 4.74 (c) pH = 6.58 (d) pH = 8.81 (e) pH = 11.03 (f) pH = 12.42 **17.47** (a) pH = 7.00 (b) $[HONH_3^+] = 0.100\ M$, pH = 3.52 (c) $[C_6H_5NH_3^+] = 0.100\ M$, pH = 2.82 **17.49** (a) True (b) false (c) false (d) true **17.51** (a) The concentration of undissolved solid does not appear in the solubility product expression because it is constant. (b) $K_{sp} = [Ag^+][I^-]$; $K_{sp} = [Sr^{2+}][SO_4^{2-}]$; $K_{sp} = [Fe^{2+}][OH^-]^2$; $K_{sp} = [Hg_2^{2+}][Br^-]^2$ **17.53** (a) $K_{sp} = 7.63 \times 10^{-9}$ (b) $K_{sp} = 2.7 \times 10^{-9}$ (c) 5.3×10^{-4} mol $Ba(IO_3)_2$/L **17.55** $K_{sp} = 2.3 \times 10^{-9}$ **17.57** (a) 7.1×10^{-7} mol AgBr/L (b) 1.7×10^{-11} mol AgBr/L (c) 5.0×10^{-12} mol AgBr/L **17.59** (a) The amount of $CaF_2(s)$ on the bottom of the beaker increases. (b) The $[Ca^{2+}]$ in solution increases. (c) The $[F^-]$ in solution decreases. **17.61** (a) 1.4×10^3 g $Mn(OH)_2$/L (b) 0.014 g/L (c) 3.6×10^{-7} g/L **17.63** More soluble in acid: (a) $ZnCO_3$ (b) ZnS (d) AgCN (e) $Ba_3(PO_4)_2$ **17.65** $[Ni^{2+}] = 1 \times 10^{-8}\ M$ **17.67** (a) 9.1×10^{-9}mol AgI per L pure water (b) $K = K_{sp} \times K_f = 8 \times 10^4$ (c) 0.0500 mol AgI per L 0.100 *M* NaCN **17.69** (a) $Q < K_{sp}$; no $Ca(OH)_2$ precipitates (b) $Q < K_{sp}$; no Ag_2SO_4 precipitates **17.71** pH = 11.5 **17.73** AgI will precipitate first, at $[I^-] = 4.2 \times 10^{-13} M$. **17.75** AgCl will precipitate first. **17.77** The first two experiments eliminate group 1 and 2 ions (Figure 17.23). The absence of insoluble phosphate precipitates in the filtrate from the third experiment rules out group 4 ions. The ions that might be in the sample are those from group 3, Al^{3+}, Fe^{3+}, Cr^{3+}, Zn^{2+}, Ni^{2+}, Mn^{2+}, or Co^{2+}, and from group 5, NH_4^+, Na^+, or K^+. **17.79** (a) Make the solution acidic with 0.2 *M* HCl; saturate with H_2S. CdS will precipitate; ZnS will not. (b) Add excess base; $Fe(OH)_3(s)$ precipitates, but Cr^{3+} forms the soluble complex $Cr(OH)_4^-$. (c) Add $(NH_4)_2HPO_4$; Mg^{2+} precipitates as $MgNH_4PO_4$; K^+ remains soluble. (d) Add 6 *M* HCl; precipitate Ag^+ as $AgCl(s)$; Mn^{2+} remains soluble. **17.81** (a) Base is required to increase $[PO_4^{3-}]$ so that the solubility product of the metal phosphates of interest is exceeded and the phosphate salts precipitate. (b) K_{sp} for the cations in group 3 is much larger; to exceed K_{sp}, a higher $[S^{2-}]$ is required. (c) They should all redissolve in strongly acidic solution. **17.83** pOH = pK_b + log $\{[BH^-]/[B]\}$ **17.89** (a) 6.5 mL glacial acetic acid, 5.25 g CH_3COONa **17.91** (a) The molecular weight of the acid is 94.6 g/mol. (b) $K_a = 1.4 \times 10^{-3}$ **17.97** (a) A person breathing normally exhales $CO_2(g)$. Rapid breathing causes excess $CO_2(g)$ to be removed from the blood. This causes both equilibria in Equation 17.10 to shift right, reducing $[H^+]$ in the blood and raising blood pH. (b) When a person breaths into a paper bag, the gas in the bag contains more CO_2 than ambient air. When the person inhales gas from the bag, a greater-than-normal partial pressure of $CO_2(g)$ in the lungs shifts the equilibria left, increasing $[H^+]$ and lowering blood pH. **17.102** The solubility of $Mg(OH)_2$ in 0.50 *M* NH_4Cl is 0.11 mol/L **17.108** $[OH^-] \geq 1.0 \times 10^{-2} M$ or pH ≥ 12.02 **17.111** (a) The molecular weight of the acid is 94.5 g/mol. (b) $K_a = 1.3 \times 10^{-5}$ (c) From Appendix D, butanoic acid is the closest match for K_a and molar mass, but the agreement is not exact. **17.113** (a) At the conditions given for the stomach, 99.7% of the aspirin is present as neutral molecules. **17.117** (a) $[Ag^+]$ from AgCl is 1.4×10^3 ppb or 1.4 ppm. (b) $[Ag^+]$ from AgBr is 76 ppb. (c) $[Ag^+]$ from AgI is 0.98 ppb. AgBr would maintain $[Ag^+]$ in the correct range.

Chapter 18

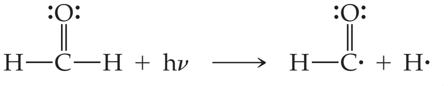
18.1 (a) A volume greater than 22.4 L (b) No. The relative volumes of one mole of an ideal gas at 50 km and 85 km depend on the temperature and pressure at the two altitudes. From Figure 18.1, the gas will occupy a much larger volume at 85 km than at 50 km. (c) We expect gases to behave most ideally in the thermosphere, around the stratopause and in the troposphere at low altitude. **18.3** (a) A = troposphere, 0–10 km; B = stratosphere, 12–50 km; C = mesosphere, 50–85 km (b) Ozone is a pollutant in the troposphere and filters UV radiation in the stratosphere. (c) The troposphere (d) Only region C in the diagram is involved in an aurora borealis, assuming a narrow "boundary" between the stratosphere and mesosphere at 50 km. (e) The concentration of water vapor is greatest near Earth's surface in region A and decreases with altitude. Water's single bonds are susceptible to photodissociation in regions B and C, so its concentration is likely to be very low in these regions. The relative concentration of CO_2, with strong double bonds, increases in regions B and C, because it is less susceptible to photodissociation. **18.5** The Sun **18.7** $CO_2(g)$ dissolves in seawater to form $H_2CO_3(aq)$. The basic pH of the ocean encourages ionization of $H_2CO_3(aq)$ to form $HCO_3^-(aq)$ and $CO_3^{2-}(aq)$. Under the correct conditions, carbon is removed from the ocean as $CaCO_3(s)$ (sea shells, coral, chalk cliffs). As carbon is removed, more $CO_2(g)$ dissolves to maintain the balance of complex and interacting acid-base and precipitation equilibria. **18.9** Above ground, evaporation of petroleum gases at the well head and waste ponds, as well as evaporation of volatile organic compounds from the ponds are potential sources of contamination. Below ground, petroleum gases and fracking liquid can migrate into groundwater, both deep and shallow aquifers. **18.11** (a) Its temperature profile (b) troposphere, 0 to 12 km; stratosphere, 12 to 50 km; mesosphere, 50 to 85 km; thermosphere, 85 to 110 km **18.13** (a) The partial pressure of O_3 is 3.0×10^{-7} atm (2.2×10^{-4} torr). (b) 7.3×10^{15} O_3 molecules/1.0 L air **18.15** 8.6×10^{16} CO molecules/1.0 L air **18.17** (a) 570 nm (b) visible electromagnetic radiation **18.19** (a) *Photodissociation* is cleavage of a bond such that two neutral species are produced. *Photoionization* is absorption of a photon with sufficient energy to eject an electron, producing an ion and the ejected electron. (b) Photoionization of O_2 requires 1205 kJ/mol. Photodissociation requires only 495 kJ/mol. At lower elevations, high-energy short-wavelength solar radiation has already been absorbed. Below 90 km, the increased concentration of O_2 and the availability of longer-wavelength radiation cause the photodissociation process to dominate. **18.21** Ozone depletion reactions, which involve only O_3, O_2, or O (oxidation state = 0), do not involve a change in oxidation state for oxygen atoms. Reactions involving ClO and one of the oxygen species with a zero oxidation state do involve a change in the oxidation state of oxygen atoms. **18.23** (a) A chlorofluorocarbon is a compound that contains chlorine, fluorine, and carbon, while a hydrofluorocarbon is a compound that contains hydrogen, fluorine, and carbon. An HFC contains hydrogen in place of the chlorine present in a CFC. (b) HFCs are potentially less harmful than CFCs because their photodissociation does not produce Cl atoms, which catalyze the destruction of ozone. **18.25** (a) The C—F bond requires more energy for dissociation than the C—Cl bond and is not readily cleaved by the available wavelengths of UV light. (b) Chlorine is present as chlorine atoms and chlorine oxide molecules, Cl and ClO, respectively. **18.27** (a) Methane, CH_4 arises from decomposition of organic matter by certain microorganisms; it also escapes from underground gas deposits. (b) SO_2 is released in volcanic gases and also is produced by bacterial action on decomposing vegetable and animal matter. (c) Nitric oxide, NO, results from oxidation of decomposing organic matter and is formed in lightning flashes.

18.29 (a)

$$H_2SO_4(aq) + CaCO_3(s) \longrightarrow CaSO_4(s) + H_2O(l) + CO_2(g)$$

(b) The $CaSO_4(s)$ would be much less reactive with acidic solution, since it would require a strongly acidic solution to shift the relevant equilibrium to the right: $CaSO_4(s) + 2H^+(aq) \rightleftharpoons Ca^{2+}(aq) + 2HSO_4^-(aq)$. $CaSO_4$ would protect $CaCO_3$ from attack by acid rain, but it would not provide the structural strength of limestone. **18.31** (a) Ultraviolet (b) 357 kJ/mol (c) The average C—H bond energy from Table 8.4 is 413 kJ/mol. The C—H bond energy in CH_2O, 357 kJ/mol, is less than the "average" C—H bond energy.

(d)



$$H{-}\overset{\overset{:\ddot{O}:}{\|}}{C}{-}H + h\nu \longrightarrow H{-}\overset{\overset{:\ddot{O}:}{\|}}{C}\cdot + H\cdot$$

18.33 Incoming and outgoing energies are in different regions of the electromagnetic spectrum. CO_2 is transparent to incoming visible radiation but absorbs outgoing infrared radiation. **18.35** 0.099 M Na^+ **18.37** (a) 3.22×10^3 gH_2O (b) The final temperature is 43.4 °C. **18.39** 4.361×10^5 g CaO **18.41** (a) *Groundwater* is freshwater (less than 500 ppm total salt content) that is under the soil; it composes 20% of the world's freshwater. (b) An *aquifer* is a layer of porous rock that holds groundwater. **18.43** The minimum pressure required to initiate reverse osmosis is greater than 5.1 atm. **18.45** (a) $CO_2(g)$, HCO_3^-, $H_2O(l)$, SO_4^{2-}, NO_3^-, HPO_4^{2-}, $H_2PO_4^-$ (b) $CH_4(g)$, $H_2S(g)$, $NH_3(g)$, $PH_3(g)$ **18.47** 25.1 g O_2

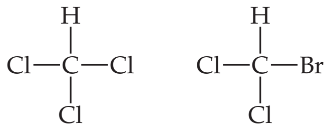
18.49 $Mg^{2+}(aq) + Ca(OH)_2(s) \longrightarrow Mg(OH)_2(s) + Ca^{2+}(aq)$

18.51 0.42 mol $Ca(OH)_2$, 0.18 mol Na_2CO_3

18.53 $4\,FeSO_4(aq) + O_2(aq) + 2\,H_2O(l) \longrightarrow$
$4\,Fe^{3+}(aq) + 4\,OH^-(aq) + 4\,SO_4^{2-}(aq)$;
$Fe^{3+}(aq) + 3HCO_3^-(aq) \longrightarrow Fe(OH)_3(s) + 3\,CO_2(g)$

18.55 (a) *Trihalomethanes* are the by-products of water chlorination; they contain one central carbon atom bound to one hydrogen and three halogen atoms.

(b)



$$Cl{-}\overset{\overset{H}{|}}{\underset{\underset{Cl}{|}}{C}}{-}Cl \qquad Cl{-}\overset{\overset{H}{|}}{\underset{\underset{Cl}{|}}{C}}{-}Br$$

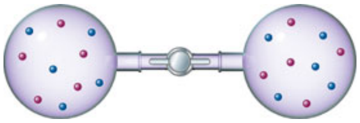
18.57 The fewer steps in a process, the less waste is generated. Processes with fewer steps require less energy at the site of the process and for subsequent cleanup or disposal of waste. **18.59** (a) H_2O (b) It is better to prevent waste than to treat it. Atom economy. Less hazardous chemical synthesis and inherently safer for accident prevention. Catalysis and design for energy efficiency. Raw materials should be renewable. **18.61** (a) Water as a solvent, by criteria 5, 7, and 12. (b) Reaction temperature of 500 K, by criteria 6, 12, and 1. (c) Sodium chloride as a by-product, according to criteria 1, 3, and 12. **18.66** Multiply Equation 18.7 by a factor of 2; then add it to Equation 18.9. 2 Cl(g) and 2 ClO(g) cancel from each side of the resulting equation to produce Equation 18.10. **18.69** (a) A CFC has C—Cl bonds and C—F bonds. In an HFC, the C—Cl bonds are replaced by C—H bonds. (b) Stratospheric lifetime is significant because, the longer a halogen-containing molecule exists in the stratosphere, the greater the likelihood that it will encounter light with energy sufficient to dissociate a carbon-halogen bond. Free halogen atoms are the bad actors in ozone destruction. (c) HFCs have replaced CFCs because it is infrequent that light with energy sufficient to dissociate a C—F bond will reach an HFC molecule. F atoms are much less likely than Cl atoms to be produced by photodissociation in the stratosphere. (d) The main disadvantage of HFCs as replacements for CFCs is that they are potent greenhouse gases. **18.71** (a) $CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(g)$ (b) $2\,CH_4(g) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 4\,H_2O(g)$ (c) 9.5 L of dry air **18.75** 7.1×10^8 m^2 **18.77** (a) CO_3^{2-} is a relatively strong Brønsted–Lowry base and produces OH^- in aqueous solution. If $[OH^-(aq)]$ is sufficient for the reaction quotient to exceed K_{sp} for $Mg(OH)_2$, the solid will precipitate. (b) At these ion concentrations, $Q > K_{sp}$ and $Mg(OH)_2$ will precipitate. **18.81** (a) 2.5×10^7 ton CO_2, 4.2×10^5 ton SO_2 (b) 4.3×10^5 ton $CaSO_3$

18.85 (a) $H{-}\underset{\cdot\cdot}{\ddot{O}}{-}H \longrightarrow H\cdot + \cdot\underset{\cdot\cdot}{\ddot{O}}{-}H$

(b) 258 nm (c) The overall reaction is $O_3(g) + O(g) \longrightarrow 2O_2(g)$. $OH(g)$ is the catalyst in the overall reaction because it is consumed and then reproduced. **18.87** The enthalpy change for the first step is −141 kJ, for the second step, −249 kJ, for the overall reaction, −390 kJ. **18.90** (a) Rate $= k[O_3][H]$ (b) $k_{avg} = 1.13 \times 10^{44}\ M^{-1}\,s^{-1}$ **18.94** (a) Process (i) is greener because it involves neither the toxic reactant phosgene nor the by-product HCl. (b) Reaction (i): C in CO_2 is linear with *sp* hybridization; C in R—N═C═O is linear with *sp* hybridization; C in the urethane monomer is trigonal planar with sp^2 hybridization. Reaction (ii): C in $COCl_2$ is trigonal planar with sp^2 hybridization; C in R—N═C═O is linear with *sp* hybridization; C in the urethane monomer is trigonal planar with sp^2 hybridization. (c) The greenest way to promote formation of the isocyanate is to remove by-product, either water or HCl, from the reaction mixture.

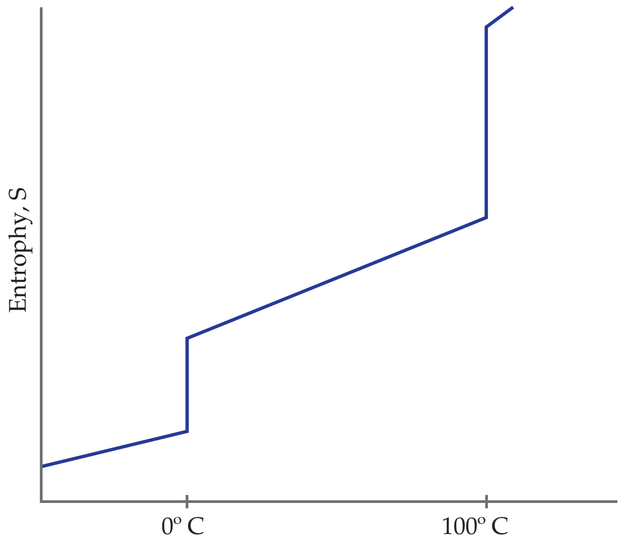
Chapter 19

19.1(a)



(b) $\Delta H = 0$ for mixing ideal gases. ΔS is positive because the disorder of the system increases. (c) The process is spontaneous and therefore irreversible. (d) Since $\Delta H = 0$, the process does not affect the entropy of the surroundings. **19.4** Both ΔH and ΔS are positive. The net change in the chemical reaction is the breaking of five blue-blue bonds. Enthalpies for bond breaking are always positive. There are twice as many molecules of gas in the products, so ΔS is positive for this reaction. **19.7** (a) At 300 K, $\Delta G = 0$, and the system is at equilibrium. (b) The reaction is spontaneous at temperatures above 300 K. **19.10** (a) True (b) false (c) false (d) false (e) true **19.11** Spontaneous: a, b, c, d; nonspontaneous: e **19.13** (a) Yes. If ΔS is large and positive, ΔG can be negative even if ΔH is positive. (b) Yes. Phase changes are examples of this. **19.15** (a) Endothermic (b) above 100 °C (c) below 100 °C (d) at 100 °C **19.17** (a) False (b) true (c) false (d) false **19.19** (a) No. Temperature is a state function, so a change in temperature does not depend on pathway. (b) No. An isothermal process occurs at constant temperature. (c) No. ΔE is a state function. **19.21** (a) An ice cube can melt reversibly at the conditions of temperature and pressure where the solid and liquid are in equilibrium. (b) We know that melting is a process that increases the energy of the system even though there is no change in temperature. ΔE is not zero for the process. **19.23** (a) True (b) true (c) false **19.25** (a) Entropy increases. (b) 89.2 J/K **19.27** (a) False (b) true (c) false **19.29** (a) Positive ΔS (b) $\Delta S = 1.02$ J/K (c) Temperature need not be specified to calculate ΔS, as long as the expansion is isothermal. **19.31** (a) Yes, the expansion is spontaneous. (b) As the ideal gas expands into the vacuum, there is nothing for it to "push back," so no work is done. Mathematically, $w = -P_{ext}\Delta V$. Since the gas expands into a vacuum, $P_{ext} = 0$ and $w = 0$. (c) The "driving force" for the expansion of the gas is the increase in entropy. **19.33** (a) An increase in temperature produces more available microstates for a system. (b) A decrease in volume produces fewer available microstates for a system. (c) Going from liquid to gas, the number of available microstates increases. **19.35** (a) ΔS is positive. (b) S of the system clearly increases in 19.11 (b) and (e); it clearly decreases in 19.11 (c). The entropy change is difficult to judge in 19.11 (a) and definition of the system in (d) is problematic. **19.37** S increases in (a) and (c); S decreases in (b). **19.39** (a) False (b) true (c) false (d) true **19.41** (a) Ar(g) (b) He(g) at 1.5 atm (c) 1 mol of Ne(g) in 15.0 L (d) $CO_2(g)$ **19.43** (a) $\Delta S < 0$ (b) $\Delta S > 0$ (c) $\Delta S < 0$ (d) $\Delta S \approx 0$

19.45 (a)



(b) Boiling water, at 100 °C, has a much larger entropy change than melting ice at 0 °C. **19.47** (a) $C_2H_6(g)$ (b) $CO_2(g)$ **19.49** (a) Sc(s), 34.6 J/mol-K; Sc(g), 174.7 J/mol-K. In general, the gas phase of a substance has a larger $S°$ than the solid phase because of the greater volume and motional freedom of the molecules. (b) $NH_3(g)$, 192.5 J/mol-K; $NH_3(aq)$, 111.3 J/mol-K. Molecules in the gas phase have more motional freedom than molecules in solution. (c) 1 mol of $P_4(g)$, 280 J/K; 2 mol of $P_2(g)$, 2(218.1) = 436.2 J/K. More particles have a greater motional energy (more available microstates). (d) C (diamond), 2.43 J/mol-K; C (graphite), 5.69 J/mol-K. The internal entropy in graphite is greater because there is translational freedom among planar sheets of C atoms, while there is very little freedom within the covalent-network diamond lattice. **19.51** For elements with similar structures, the heavier the atoms, the lower the vibrational frequencies at a given temperature. This means that more vibrations can be accessed at a particular temperature, resulting in greater absolute entropy for the heavier elements. **19.53** (a) $\Delta S° = -120.5$ J/K. $\Delta S°$ is negative because there are fewer moles of gas in the products. (b) $\Delta S° = +176.6$ J/K. $\Delta S°$ is positive because there are more moles of gas in the products. (c) $\Delta S° = +152.39$ J/K. $\Delta S°$ is positive because the product contains more total particles and more moles of gas. (d) $\Delta S° = +92.3$ J/K. $\Delta S°$ is positive because there are more moles of gas in the products. **19.55** (a) Yes. $\Delta G = \Delta H - T\Delta S$ (b) No. If ΔG is positive, the process is nonspontaneous. (c) No. There is no relationship between ΔG and rate of reaction. **19.57** (a) Exothermic (b) $\Delta S°$ is negative; the reaction leads to a decrease in disorder. (c) $\Delta G° = -9.9$ kJ (d) If all reactants and products are present in their standard states, the reaction is spontaneous in the forward direction at this temperature. **19.59** (a) $\Delta H° = -537.22\ kJ$, $\Delta S° = 13.7$ J/K, $\Delta G° = -541.40$ kJ, $\Delta G° = \Delta H° - T\Delta S° = -541.31$ kJ (b) $\Delta H° = -106.7$ kJ, $\Delta S° = -142.2$ kJ, $\Delta G° = -64.0$ kJ, $\Delta G° = \Delta H° - T\Delta S° = -64.3$ kJ (c) $\Delta H° = -508.3$ kJ, $\Delta S° = -178$ kJ, $\Delta G° = -465.8$ kJ, $\Delta G° = \Delta H° - T\Delta S° = -455.1$ kJ. The discrepancy in $\Delta G°$ values is due to experimental uncertainties in the tabulated thermodynamic data. (d) $\Delta H° = -165.9$ kJ, $\Delta S° = 1.4$ kJ, $\Delta G° = -166.2$ kJ, $\Delta G° = \Delta H° - T\Delta S° = -166.3$ kJ **19.61** (a) $\Delta G° = -140.0$ kJ, spontaneous (b) $\Delta G° = +104.70$ kJ, nonspontaneous (c) $\Delta G° = +146$ kJ, nonspontaneous (d) $\Delta G° = -156.7$ kJ, spontaneous

19.63 (a) $2\,C_8H_{18}(l) + 25\,O_2(g) \longrightarrow 16\,CO_2(g) + 18\,H_2O(l)$
(b) Because $\Delta S°$ is positive, $\Delta G°$ is more negative than $\Delta H°$.

19.65 (a) The forward reaction is spontaneous at low temperatures but becomes nonspontaneous at higher temperatures. (b) The reaction is nonspontaneous in the forward direction at all temperatures. (c) The forward reaction is nonspontaneous at low temperatures but becomes spontaneous at higher temperatures. **19.67** $\Delta S > 60.8$ J/K **19.69** (a) $T = 330$ K (b) nonspontaneous **19.71** (a) $\Delta H° = 155.7$ kJ, $\Delta S° = 171.4$ kJ. Since $\Delta S°$ is positive, $\Delta G°$ becomes more negative with increasing temperature. (b) $\Delta G° = 19$ kJ. The reaction is not spontaneous under standard conditions at 800 K (c) $\Delta G° = -15.7$ kJ. The reaction is spontaneous under standard conditions at 1000 K. **19.73** (a) $T_b = 79$ °C (b) From the *Handbook of Chemistry and Physics*, 74th Edition, $T_b = 80.1$ °C. The values are remarkably close; the small difference is due to deviation from ideal behavior by $C_6H_6(g)$ and experimental uncertainty in the boiling point measurement and the thermodynamic data.

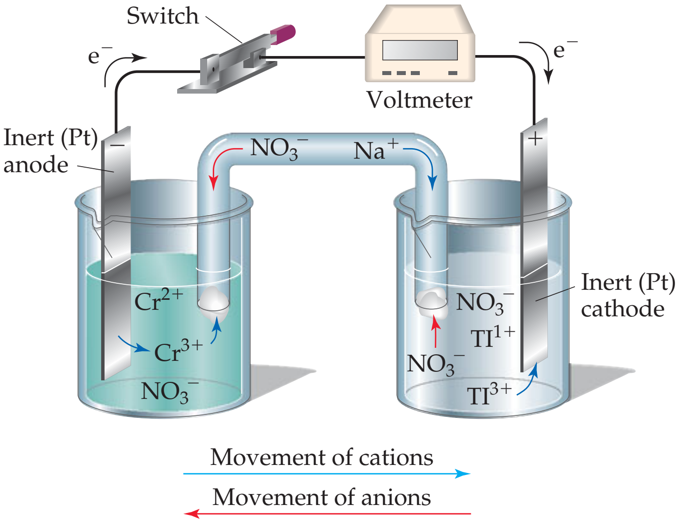
19.75 (a) $C_2H_2(g) + \frac{5}{2}O_2(g) \longrightarrow 2\,CO_2(g) + H_2O(l)$
(b) −1299.5 kJ of heat produced/mol C_2H_2 burned (c) $w_{max} = -1235.1$ kJ/mol C_2H_2 **19.77** (a) ΔG decreases; it becomes more negative. (b) ΔG increases; it becomes more positive. (c) ΔG increases; it becomes more positive. **19.79** (a) $\Delta G° = -5.40$ kJ (b) $\Delta G = 0.30$ kJ **19.81** (a) $\Delta G° = -16.77$ kJ, $K = 870$ (b) $\Delta G° = 8.0$ kJ, $K = 0.039$ (c) $\Delta G° = -497.9$ kJ, $K = 2 \times 10^{87}$

19.83 $\Delta H° = 269.3$ kJ, $\Delta S° = 0.1719$ kJ/K
(a) $P_{CO_2} = 6.0 \times 10^{-39}$ atm (b) $P_{CO_2} = 1.6 \times 10^{-4}$ atm

19.85 (a) $HNO_2(aq) \rightleftharpoons H^+(aq) + NO_2^-(aq)$ (b) $\Delta G° = 19.1$ kJ (c) $\Delta G = 0$ at equilibrium (d) $\Delta G = -2.7$ kJ **19.87** (a) The thermodynamic quantities T, E, and S are state functions. (b) The quantities q and w depend on the path taken. (c) There is only one *reversible* path between states. (d) $\Delta E = q_{rev} + w_{max}$, $\Delta S = q_{rev}/T$. **19.91** (a) 16 arrangements (b) 1 arrangement (c) The gas will spontaneously adopt the state with the most possible arrangements for the molecules, the state with maximum disorder. **19.96** (a) For all three compounds listed, there are fewer moles of gaseous products than reactants in the formation reaction, so we expect ΔS_f° to be negative. If $\Delta G_f^\circ = \Delta H_f^\circ - T\Delta S_f^\circ$ and ΔS_f° is negative, $-T\Delta S_f^\circ$ is positive and ΔG_f° is more positive than ΔH_f°. (b) In this reaction, there are more moles of gas in products, ΔS_f° is positive, $-T\Delta S_f^\circ$ is negative and ΔG_f° is more negative than ΔH_f°. **19.101** (a) For the oxidation of glucose in the body, $\Delta G^\circ = -2878.8$ kJ, $K = 5 \times 10^{504}$; for the anaerobic decomposition of glucose, $\Delta G^\circ = -228.0$ kJ, $K = 9 \times 10^{39}$ (b) A greater maximum amount of work at standard conditions can be obtained from the oxidation of glucose in the body, because ΔG° is much more negative. **19.104** (a) $\Delta G = 8.77$ kJ (b) $w_{min} = 8.77$ kJ. In practice, a larger than minimum amount of work is required. **19.107** (a) Acetone, $\Delta S_{vap}^\circ = 88.4$ J/mol-K; dimethyl ether, $\Delta S_{vap}^\circ = 86.6$ J/mol-K; ethanol, $\Delta S_{vap}^\circ = 110$ J/mol-K; octane, $\Delta S_{vap}^\circ = 86.3$ J/mol-K; pyridine, $\Delta S_{vap}^\circ = 90.4$ J/mol-K. Ethanol does not obey Trouton's rule. (b) Hydrogen bonding (in ethanol and other liquids) leads to more ordering in the liquid state and a greater than usual increase in entropy upon vaporization. Liquids that experience hydrogen bonding are probably exceptions to Trouton's rule. (c) Owing to strong hydrogen bonding interactions, water probably does not obey Trouton's rule. $\Delta S_{vap}^\circ = 109.0$ J/mol-K. (d) ΔH_{vap} for $C_6H_5Cl \approx 36$ kJ/mol **19.114** (a) For any given total pressure, the condition of equal moles of the two gases can be achieved at some temperature. For individual gas pressures of 1 atm and a total pressure of 2 atm, the mixture is at equilibrium at 328.5 K or 55.5 °C. (b) 333.0 K or 60 °C (c) 374.2 K or 101.2 °C (d) The reaction is endothermic, so an increase in the value of K as calculated in parts (a)–(c) should be accompanied by an increase in T.

Chapter 20

20.1 In this analogy, the electron is analogous to the proton (H^+). Redox reactions can be viewed as electron-transfer reactions, just as acid-base reactions can be viewed as proton-transfer reactions. Oxidizing agents are themselves reduced; they gain electrons. A strong oxidizing agent would be analogous to a strong base. **20.3** (a) The process represents oxidation (b) The electrode is the anode. (c) When a neutral atom loses a valence electron, the radius of the resulting cation is smaller than the radius of the neutral atom. **20.7** (a) The sign of ΔG° is positive. (b) The equilibrium constant is less than one. (c) No. An electrochemical cell based on this reaction cannot accomplish work on its surroundings. **20.10** (a) Zinc is the anode. (b) The energy density of the silver oxide battery is most similar to the nickel-cadmium battery. The molar masses of the electrode materials and the cell potentials for these two batteries are most similar. **20.13** (a) *Oxidation* is the loss of electrons. (b) Electrons appear on the products' side (right side). (c) The *oxidant* is the reactant that is reduced. (d) An *oxidizing agent* is the substance that promotes oxidation; it is the oxidant. **20.15** (a) True (b) false (c) true **20.17** (a) I, +5 to 0; C, +2 to +4 (b) Hg, +2 to 0; N, −2 to 0 (c) N, +5 to +2; S, −2 to 0 **20.19** (a) No oxidation-reduction (b) Iodine is oxidized; chlorine is reduced. (c) Sulfur is oxidized; nitrogen is reduced. **20.21** (a) $TiCl_4(g) + 2\,Mg(l) \longrightarrow Ti(s) + 2\,MgCl_2(l)$ (b) $Mg(l)$ is oxidized; $TiCl_4(g)$ is reduced. (c) $Mg(l)$ is the reductant; $TiCl_4(g)$ is the oxidant. **20.23** (a) $Sn^{2+}(aq) \longrightarrow Sn^{4+}(aq) + 2\,e^-$, oxidation (b) $TiO_2(s) + 4\,H^+(aq) + 2\,e^- \longrightarrow Ti^{2+}(aq) + 2\,H_2O(l)$, reduction (c) $ClO_3^-(aq) + 6\,H^+(aq) + 6\,e^- \longrightarrow Cl_2(aq) + 3\,H_2O(l)$, reduction (d) $N_2(g) + 8\,H^+(aq) + 6\,e^- \longrightarrow 2\,NH_4^+(aq)$, reduction (e) $4\,OH^-(aq) \longrightarrow O_2(g) + 2\,H_2O(l) + 4\,e^-$, oxidation (f) $SO_3^{2-}(aq) + 2\,OH^-(aq) \longrightarrow SO_4^{2-}(aq) + H_2O(l) + 2\,e^-$, oxidation (g) $N_2(g) + 6\,H_2O(l) + 6\,e^- \longrightarrow 2\,NH_3(g) + 6\,OH^-(aq)$, reduction **20.25** (a) $Cr_2O_7^{2-}(aq) + I^-(aq) + 8\,H^+(aq) \longrightarrow 2\,Cr^{3+}(aq) + IO_3^-(aq) + 4\,H_2O(l)$; oxidizing agent, $Cr_2O_7^{2-}$; reducing agent, I^- (b) $4\,MnO_4^-(aq) + 5\,CH_3OH(aq) + 12\,H^+(aq) \longrightarrow 4\,Mn^{2+}(aq) + 5\,HCO_2H(aq) + 12\,H_2O(aq)$; oxidizing agent, MnO_4^-; reducing agent, CH_3OH (c) $I_2(s) + 5\,OCl^-(aq) + H_2O(l) \longrightarrow 2\,IO_3^-(aq) + 5\,Cl^-(aq) + 2\,H^+(aq)$; oxidizing agent, OCl^-; reducing agent, I_2 (d) $As_2O_3(s) + 2\,NO_3^-(aq) + 2\,H_2O(l) + 2\,H^+(aq) \longrightarrow 2\,H_3AsO_4(aq) + N_2O_3(aq)$; oxidizing agent, NO_3^-; reducing agent, As_2O_3 (e) $2MnO_4^-(aq) + Br^-(aq) + H_2O(l) \longrightarrow 2MnO_2(s) + BrO_3^-(aq) + 2OH^-(aq)$, oxidizing agent, MnO_4^-; reducing agent, Br^- (f) $Pb(OH)_4^{2-}(aq) + ClO^-(aq) \longrightarrow PbO_2(s) + Cl^-(aq) + 2\,OH^-(aq) + H_2O(l)$; oxidizing agent, $ClO^-(aq)$; reducing agent, $Pb(OH)_4^{2-}$ **20.27** (a) The reaction $Cu^{2+}(aq) + Zn(s) \longrightarrow Cu(s) + Zn^{2+}(aq)$ is occurring in both figures. In Figure 20.3 the reactants are in contact, while in Figure 20.4 the oxidation half-reaction and reduction half-reaction are occurring in separate compartments. In Figure 20.3 the flow of electrons cannot be isolated or utilized; in Figure 20.4 electrical current is isolated and flows through the voltmeter. (b) Na^+ cations are drawn into the cathode compartment to maintain charge balance as Cu^{2+} ions are removed. **20.29** (a) $Fe(s)$ is oxidized, $Ag^+(aq)$ is reduced. (b) $Ag^+(aq) + e^- \longrightarrow Ag(s)$; $Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$. (c) $Fe(s)$ is the anode, $Ag(s)$ is the cathode. (d) $Fe(s)$ is negative; $Ag(s)$ is positive. (e) Electrons flow from the Fe electrode (−) toward the Ag electrode (+). (f) Cations migrate toward the $Ag(s)$ cathode; anions migrate toward the $Fe(s)$ anode. **20.31** *Electromotive force*, emf, is the potential energy difference between an electron at the anode and an electron at the cathode of a voltaic cell. (b) One *volt* is the potential energy difference required to impart 1 J of energy to a charge of 1 coulomb. (c) *Cell potential*, E_{cell}, is the emf of an electrochemical cell. **20.33** (a) $2\,H^+(aq) + 2e^- \longrightarrow H_2(g)$ (b) $H_2(g) \longrightarrow 2\,H^+(aq) + 2e^-$ (c) A *standard* hydrogen electrode, SHE, has components that are at standard conditions, 1 *M* $H^+(aq)$ and $H_2(g)$ at 1 atm. (c) The platinum foil in a SHE serves as an inert electron carrier and a solid reaction surface. **20.35** (a)
$Cr^{2+}(aq) \longrightarrow Cr^{3+}(aq) + e^-$; $Tl^{3+}(aq) + 2\,e^- \longrightarrow Tl^+(aq)$
(b) $E_{red}^\circ = 0.78$ *V*
(c)



20.37 (a) $E^\circ = 0.823$ V (b) $E^\circ = 1.89$ V (c) $E^\circ = 1.211$ V. (d) $E^\circ = 0.62$ V **20.39** (a) $3\,Ag^+(aq) + Cr(s) \longrightarrow 3\,Ag(s) + Cr^{3+}(aq)$, $E^\circ = 1.54$ V (b) Two of the combinations have essentially equal E° values: $2\,Ag^+(aq) + Cu(s) \longrightarrow 2\,Ag(s) + Cu^{2+}(aq)$, $E^\circ = 0.462$ V; $3\,Ni^{2+}(aq) + 2\,Cr(s) \longrightarrow 3\,Ni(s) + 2\,Cr^{3+}(aq)$, $E^\circ = 0.46$ V **20.41** (a) Anode, $Sn(s)$; cathode, $Cu(s)$. (b) The copper electrode gains mass as Cu is plated out, and the tin electrode loses mass as Sn is oxidized.
(c) $Cu^{2+}(aq) + Sn(s) \longrightarrow Cu(s) + Sn^{2+}(aq)$. (d) $E^\circ = 0.473$ V. **20.43** (a) $Mg(s)$ (b) $Ca(s)$ (c) $H_2(g)$ (d) $BrO_3^-(aq)$ **20.45** (a) $Cl_2(aq)$, strong oxidant (b) $MnO_4^-(aq)$, acidic, strong oxidant (c) $Ba(s)$ strong reductant (d) $Zn(s)$, reductant

20.47 (a) $Cu^{2+}(aq) < O_2(g) < Cr_2O_7^{2-}(aq) < Cl_2(g) < H_2O_2(aq)$ (b) $H_2O_2(aq) < I^2(aq) < Sn^{2+}(aq) < Zn(s) < Al(s)$ **20.49** Al and $H_2C_2O_4$ **20.51** (a) $2\,Fe^{2+}(aq) + S_2O_6^{2-}(aq) + 4\,H^+(aq) \longrightarrow 2\,Fe^{3+}(aq) + 2\,H_2SO_3(aq)$; $2\,Fe^{2+}(aq) + N_2O(aq) + 2\,H^+(aq) \longrightarrow 2\,Fe^{3+}(aq) + N_2(g) + H_2O(l)$; $Fe^{2+}(aq) + VO_2^+(aq) + 2\,H^+(aq) \longrightarrow Fe^{3+}(aq) + VO^{2+}(aq) + H_2O(l)$ (b) $E° = -0.17$ V, $\Delta G° = 33$ kJ; $E° = -2.54$ V, $\Delta G° = 4.90 \times 10^2$ kJ; $E° = 0.23$ V, $\Delta G° = -22$ kJ (c) $K = 1.8 \times 10^{-6} = 10^{-6}$; $K = 1.2 \times 10^{-86} = 10^{-86}$; $K = 7.8 \times 10^3 = 8 \times 10^3$ **20.53** $\Delta G° = 21.8$ kJ, $E°_{cell} = -0.113\ V$ **20.55** (a) $E° = 0.16$ V, $K = 2.54 \times 10^5 = 3 \times 10^5$ (b) $E° = 0.277$ V, $K = 2.3 \times 10^9$ (c) $E° = 0.45$ V, $K = 1.5 \times 10^{75} = 10^{75}$ **20.57** (a) $K = 9.8 \times 10^2$ (b) $K = 9.5 \times 10^5$ (c) $K = 9.3 \times 10^8$ **20.59** $w_{max} = -130$ kJ/mol Sn **20.61** (a) In the Nernst equation, $Q = 1$ if all reactants and products are at standard conditions. (b) Yes. The Nernst equation is applicable to cell emf at nonstandard conditions, so it must be applicable at temperatures other than 298 K. Values of $E°$ at temperatures other than 298 K are required. And, there is a variable for T in the second term. If the short-hand form of the equation, Equation 20.18, is used, a coefficient other than 0.0592 is required. **20.63** (a) E decreases (b) E decreases (c) E decreases (d) no effect **20.65** (a) $E° = 0.48$ V (b) $E = 0.53$ V (c) $E = 0.46$ V **20.67** (a) $E° = 0.46$ V (b) $E = 0.37$ V **20.69** (a) The compartment with $[Zn^{2+}] = 1.00 \times 10^{-2}\,M$ is the anode. (b) $E° = 0$ (c) $E = 0.0668$ V (d) In the anode compartment $[Zn^{2+}]$ increases; in the cathode compartment $[Zn^{2+}]$ decreases **20.71** $E° = 0.763$ V, pH = 1.6 **20.73** (a) 464 g PbO_2 (b) 3.74×10^5 C of charge transferred **20.75** (a) The anode (b) $E° = 0.50$ V (c) The emf of the battery, 3.5 V, is exactly the standard cell potential calculated in part (b). (d) At ambient conditions, $E \approx E°$, so $\log Q \approx 1$. Assuming that the value of $E°$ is relatively constant with temperature, the value of the second term in the Nernst equation is approximately zero at 37 °C, and $E \approx 3.5$ V. **20.77** (a) The cell emf will have a smaller value. (b) NiMH batteries use an alloy such as $ZrNi_2$ as the anode material. This eliminates the use and disposal problems associated with Cd, a toxic heavy metal. **20.79** (a) When the battery is fully charged, the mole ratio of the elements in the cathode is: 0.5 mol Li^+ to 0.5 mol Co^{3+} to 0.5 mol Co^{4+} to 2 mol O^{2-}. (b) 4.9×10^3 C of electricity delivered on full discharge of a fully charged battery **20.81** The main advantage of a fuel cell is that fuel is continuously supplied, so that it can produce electrical current for a time limited only by the amount of available fuel. For the hydrogen-oxygen fuel cell, this is also a disadvantage because volatile and explosive hydrogen must be acquired and stored. Alkaline batteries are convenient, but they have a short lifetime, and the disposal of their zinc and manganese solids is more problematic than disposal of water produced by the hydrogen-oxygen fuel cell. **20.83** (a) anode: $Fe(s) \longrightarrow Fe^{2+}(aq) + 2\,e^-$; cathode: $O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l)$ (b) $2\,Fe^{2+}(aq) + 3\,H_2O(l) + 3\,H_2O(l) \longrightarrow Fe_2O_3 \cdot 3\,H_2O(s) + 6\,H^+(aq) + 2\,e^-$; $O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l)$ **20.85** (a) Mg is called a "sacrificial anode" because it has a more negative $E°_{red}$ than the pipe metal and is preferentially oxidized when the two are coupled. It is sacrificed to preserve the pipe. (b) $E°_{red}$ for Mg^{2+} is −2.37 V, more negative than most metals present in pipes, including Fe and Zn. **20.87** Under acidic conditions, air (O_2) oxidation of Zn(*s*), 1.99 V; Fe(*s*), 1.67 V; and Cu(*s*), 0.893 V are all spontaneous. When the three metals are in contact, Zn will act as a sacrificial anode for both Fe and Cu, but after the Zn is depleted, Fe will be oxidized (corroded). **20.89** (a) *Electrolysis* is an electrochemical process driven by an outside energy source. (b) By definition, electrolysis reactions are nonspontaneous. (c) $2\,Cl^-(l) \longrightarrow Cl_2(g) + 2\,e^-$ (d) When an aqueous solution of NaCl undergoes electrolysis, sodium metal is not formed because H_2O is preferentially reduced to form $H_2(g)$. **20.91** (a) 236 g Cr(*s*) (b) 2.51 A **20.93** (a) 4.0×10^5 g Li (b) The minimum voltage required to drive the electrolysis is +4.41 V. **20.95** Gold is less active than copper and thus more difficult to oxidize. When crude copper is refined by electrolysis, Cu is oxidized from the crude anode, but any metallic gold present in the crude copper is not oxidized,so it accumulates near the anode, available for collection. **20.97** (a) $2\,Ni^+(aq) \longrightarrow Ni(s) + Ni^{2+}(aq)$ (b) $3\,MnO_4^{2-}(aq) + 4\,H^+(aq) \longrightarrow 2\,MnO_4^-(aq) + MnO_2(s) + 2\,H_2O(l)$ (c) $3\,H_2SO_3(aq) \longrightarrow S(s) + 2\,HSO_4^-(aq) + 2\,H^+(aq) + H_2O(l)$ (d) $Cl_2(aq) + 2\,OH^-(aq) \longrightarrow Cl^-(aq) + ClO^-(aq) + H_2O(l)$ **20.99** (a) $E° = 0.627$ V, spontaneous (b) $E° = -0.82$ V, nonspontaneous (c) $E° = 0.93$ V, spontaneous (d) $E° = 0.183$ V, spontaneous **20.103** $K = 1.6 \times 10^6$ **20.106** The ship's hull should be made negative. The ship, as a negatively charged "electrode," becomes the site of reduction, rather than oxidation, in an electrolytic process. **20.109** 3×10^4 kWh required **20.114** (a) $E° = 0.028$ V (b) cathode: $Ag^+(aq) + e^- \longrightarrow Ag(s)$; anode: $Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + e^-$ (c) $\Delta S° = 148.5$ J. Since $\Delta S°$ is positive, $\Delta G°$ will become more negative and $E°$ will become more positive as temperature is increased. **20.117** K_{sp} for AgSCN is 1.0×10^{-12}.

Chapter 21

21.1 (a) ^{24}Ne; outside; reduce neutron-to-proton ratio via β decay (b) ^{32}Cl; outside; increase neutron-to-proton ratio via positron emission or orbital electron capture (c) ^{108}Sn; outside; increase neutron-to-proton ratio via positron emission or orbital electron capture (d) ^{216}Po; outside; nuclei with $Z \geq 84$ usually decay via α emission. **21.6** (a) 7 min (b) 0.1 min^{-1} (c) 30% (3/10) of the sample remains after 12 min. (d) $^{88}_{41}Nb$ **21.7** (a) $^{10}_{5}B$, $^{11}_{5}B$; $^{12}_{6}C$, $^{13}_{6}C$; $^{14}_{7}N$, $^{15}_{7}N$; $^{16}_{8}O$, $^{17}_{8}O$, $^{18}_{8}O$; $^{19}_{9}F$ (b) $^{14}_{6}C$ (c) $^{11}_{6}C$, $^{13}_{7}N$, $^{15}_{8}O$, $^{18}_{9}F$ (d) $^{11}_{6}C$ **21.9** (a) 24 protons, 32 neutrons (b) 81 protons, 112 neutrons (c) 18 protons, 20 neutrons **21.11** (a) $^{1}_{0}n$ (b) $^{4}_{2}He$ or α (c) $^{0}_{0}\gamma$ or γ **21.13** (a) $^{90}_{37}Rb \longrightarrow {}^{90}_{38}Sr + {}^{0}_{-1}e$ (b) $^{72}_{34}Se + {}^{0}_{-1}e$ (orbital electron) $\longrightarrow {}^{72}_{33}As$ (c) $^{76}_{36}Kr \longrightarrow {}^{76}_{35}Br + {}^{0}_{1}e$ (d) $^{226}_{88}Ra \longrightarrow {}^{222}_{86}Rn + {}^{4}_{2}He$ **21.15** (a) $^{211}_{82}Pb \longrightarrow {}^{211}_{83}Bi + {}^{0}_{-1}\beta$ (b) $^{50}_{25}Mn \longrightarrow {}^{50}_{24}Cr + {}^{0}_{1}e$ (c) $^{179}_{74}W + {}^{0}_{-1}e \longrightarrow {}^{179}_{73}Ta$ (d) $^{230}_{90}Th \longrightarrow {}^{266}_{88}Ra + {}^{4}_{2}He$ **21.17** 7 alpha emissions, 4 beta emissions **21.19** (a) Positron emission (for low atomic numbers, positron emission is more common than electron capture) (b) beta emission (c) beta emission (d) beta emission **21.21** (a) $^{40}_{19}K$, radioactive, odd proton, odd neutron; $^{39}_{19}K$, stable, 20 neutrons is a magic number (b) $^{208}_{83}Bi$, radioactive, odd proton, odd neutron; $^{209}_{83}Bi$, stable, 126 neutrons is a magic number (c) $^{65}_{28}Ni$, radioactive, high neutron-to-proton ratio; $^{58}_{28}Ni$ stable, even proton, even neutron **21.23** (a) $^{4}_{2}He$ (b) $^{40}_{20}Ca$ (c) $^{126}_{82}Pb$ **21.25** The alpha particle, $^{4}_{2}He$, has a magic number of both protons and neutrons, while the proton is an odd proton, even neutron particle. Alpha is a very stable emitted particle, which makes alpha emission a favorable process. The proton is not a stable emitted particle, and its formation does not encourage proton emission as a process. **21.27** Protons and alpha particles are positively charged and must be moving very fast to overcome electrostatic forces that would repel them from the target nucleus. Neutrons are electrically neutral and not repelled by the nucleus. **21.29** (a) $^{252}_{98}Cf + {}^{10}_{5}B \longrightarrow 3\,{}^{1}_{0}n + {}^{259}_{103}Lr$ (b) $^{2}_{1}H + {}^{3}_{2}He \longrightarrow {}^{4}_{2}He + {}^{1}_{1}H$ (c) $^{1}_{1}H + {}^{11}_{5}B \longrightarrow 3\,{}^{4}_{2}He$ (d) $^{122}_{53}I \longrightarrow {}^{122}_{54}Xe + {}^{0}_{-1}e$ (e) $^{59}_{26}Fe \longrightarrow {}^{0}_{-1}e + {}^{59}_{27}Co$ **21.31** (a) $^{238}_{92}U + {}^{4}_{2}He \longrightarrow {}^{241}_{94}Pu + {}^{1}_{0}n$ (b) $^{14}_{7}N + {}^{4}_{2}He \longrightarrow {}^{17}_{8}O + {}^{1}_{1}H$ (c) $^{56}_{26}Fe + {}^{4}_{2}He \longrightarrow {}^{60}_{29}Cu + {}^{0}_{-1}e$ **21.33** (a) True. The decay rate constant and half-life are inversely related. (b) False. If X is not radioactive, its half-life is essentially infinity. (c) True. Changes in the amount of A would be substantial and measurable over the 40-year time frame, while changes in the amount of X would be very small and difficult to detect. **21.35** When the watch is 50 years old, only 6% of the tritium remains. The dial will be dimmed by 94%. **21.37** The source must be replaced after 2.18 yr or 26.2 months; this corresponds to August 2015. **21.39** (a) 1.1×10^{11} alpha particles emitted in 5.0 min (b) 9.9 mCi **21.41** $k = 1.21 \times 10^{-4}\ yr^{-1}$; $t = 4.3 \times 10^3$ yr **21.43** $k = 5.46 \times 10^{-10} yr^{-1}$; $t = 3.0 \times 10^9$ yr **21.45** The energy released when one mole of Fe_2O_3 reacts is 8.515×10^5 J. The energy released when one mole of $^{4}_{2}He$ is formed from protons and neutrons is 2.73×10^{12} J. This is 3×10^6 or 3 million times as much energy as the thermite reaction.

21.47 $\Delta m = 0.2414960$ amu, $\Delta E = 3.604129 \times 10^{-11}$ J/^{27}Al nucleus required, 8.044234×10^{13}J/100 g ^{27}Al **21.49** (a) Nuclear mass: ^{2}H, 2.013553 amu; ^{4}He, 4.001505 amu; ^{6}Li, 6.0134771 amu (b) nuclear binding energy: ^{2}H, 3.564×10^{-13}J; ^{4}He, 4.5336×10^{-12} J; ^{6}Li, 5.12602×10^{-12} J. (c) binding energy/nucleon: ^{2}H, 1.782×10^{-13} J/nucleon; ^{4}He, 1.1334×10^{-12} J/nucleon; ^{6}Li, 8.54337×10^{-13} J/nucleon. This trend in binding energy/nucleon agrees with the curve in Figure 21.12. The anomalously high calculated value for ^{4}He is also apparent on the figure. **21.51** (a) 1.71×10^5 kg/d (b) 2.1×10^8 g ^{235}U **21.53** (a) ^{59}Co; it has the largest binding energy per nucleon, and binding energy gives rise to mass defect. **21.55** (a) NaI is a good source of iodine because iodine is a large percentage of its mass; it is completely dissociated into ions in aqueous solution, and iodine in the form of $I^-(aq)$ is mobile and immediately available for biouptake. (b) A Geiger counter placed near the thyroid immediately after ingestion will register background, then gradually increase in signal until the concentration of iodine in the thyroid reaches a maximum. Over time, iodine-131 decays, and the signal decreases. (c) The radioactive iodine will decay to 0.01% of the original amount in approximately 82 days. **21.57** (a) Characteristics (ii) and (iv) are required for a fuel in a nuclear power plant. (b) ^{235}U **21.59** The *control rods* in a nuclear reactor regulate the flux of neutrons to keep the reaction chain self-sustaining and also to prevent the reactor core from overheating. They are composed of materials such as boron or cadmium that absorb neutrons. **21.61** (a) ${}^{2}_{1}\text{H} + {}^{2}_{1}\text{H} \longrightarrow {}^{3}_{2}\text{He} + {}^{1}_{0}\text{n}$ (b) ${}^{239}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{133}_{51}\text{Sb} + {}^{98}_{41}\text{Nb} + 9\,{}^{1}_{0}\text{n}$

21.63 (a) $\Delta m = 0.006627$ g/mol; $\Delta E = 5.956 \times 10^{11}$J $=$ 5.956×10^8 kJ/mol ${}^{1}_{1}$H (b) The extremely high temperature is required to overcome electrostatic charge repulsions between the nuclei so that they can come together to react. **21.65** (a) Boiling water reactor (b) fast breeder reactor (c) gas-cooled reactor **21.67** Hydrogen abstraction: $\text{RCOOH} + \text{OH} \longrightarrow \text{RCOO} + \text{H}_2\text{O}$; deprotonation: $\text{RCOOH} + \text{OH}^- \longrightarrow \text{RCOO}^- + \text{H}_2\text{O}$. Hydroxyl radical is more toxic to living systems because it produces other radicals when it reacts with molecules in the organism. Hydroxide ion, OH^-, on the other hand, will be readily neutralized in the buffered cell environment. The acid–base reactions of OH^- are usually much less disruptive to the organism than the chain of redox reactions initiated by OH radical.

21.69 (a) 5.3×10^8 dis/s, 5.3×10^8 Bq
(b) 6.1×10^2 mrad, 6.1×10^{-3} Gy
(c) 5.8×10^3 mrem, 5.8×10^{-2} Sv

21.72 ${}^{210}_{82}\text{Pb}$ **21.74** (a) ${}^{36}_{17}\text{Cl} \longrightarrow {}^{36}_{18}\text{Ar} + {}^{0}_{-1}\text{e}$ (b) ^{35}Cl and ^{37}Cl both have an odd number of protons but an even number of neutrons. ^{36}Cl has an odd number of protons and neutrons, so it is less stable than the other two isotopes. **21.76** (a) ${}^{6}_{3}\text{Li} + {}^{56}_{28}\text{Ni} \longrightarrow {}^{62}_{31}\text{Ga}$ (b) ${}^{40}_{20}\text{Ca} + {}^{248}_{96}\text{Cm} \longrightarrow {}^{147}_{62}\text{Sm} + {}^{141}_{54}\text{Xe}$ (c) ${}^{88}_{38}\text{Sr} + {}^{84}_{36}\text{Kr} \longrightarrow {}^{116}_{46}\text{Pd} + {}^{56}_{28}\text{Ni}$ (d) ${}^{40}_{20}\text{Ca} + {}^{238}_{92}\text{U} \longrightarrow {}^{70}_{30}\text{Zn} + 4\,{}^{1}_{0}\text{n} + 2\,{}^{102}_{41}\text{Nb}$

21.80 $k = 9.2 \times 10^{-13}\ \text{s}^{-1}$; $N = 9.7 \times 10^{20}$ Pu atoms; rate $=$ 8.9×10^8 counts/s **21.84** ^{7}Be, 8.612×10^{-13} J/nucleon; ^{9}Be, 1.035×10^{-12} J/nucleon; ^{10}Be: 1.042×10^{-12} J/nucleon. The binding energies/ nucleon for ^{9}Be and ^{10}Be are very similar; that for ^{10}Be is slightly higher. **21.90** 1.4×10^4 kg C_8H_{18}

Chapter 22

22.1 (a) C_2H_4, the structure on the left, is the stable compound. Carbon can form strong multiple bonds to satisfy the octet rule, while silicon cannot. (b) The geometry about the central atoms in C_2H_4 is trigonal planar. **22.3** Molecules (b) and (d) will have the seesaw structure shown in the figure. **22.6** The graph shows the trend in (c) density for the group 6A elements. Going down the family, atomic mass increases faster than atomic volume (radius), and density increases. **22.9** The compound on the left, with the strained three-membered ring, will be the most generally reactive. The larger the deviation from ideal bond angles, the more strain in the molecule and the more generally reactive it is. **22.11** Metals: (b) Sr, (c) Mn, (e) Na; nonmetals: (a) P, (d) Se, (f) Kr; metalloids: none. **22.13** (a) O (b) Br (c) Ba (d) O (e) Co (f) Br **22.15** (a) N is too small a central atom to fit five fluorine atoms, and it does not have available *d* orbitals, which can help accommodate more than eight electrons. (b) Si does not readily form π bonds, which are necessary to satisfy the octet rule for both atoms in the molecule. (c) As has a lower electronegativity than N; that is, it more readily gives up electrons to an acceptor and is more easily oxidized.

22.17 (a) $\text{NaOCH}_3(s) + \text{H}_2\text{O}(l) \longrightarrow \text{NaOH}(aq) + \text{CH}_3\text{OH}(aq)$
(b) $\text{CuO}(s) + 2\,\text{HNO}_3(aq) \longrightarrow \text{Cu(NO}_3)_2(aq) + \text{H}_2\text{O}(l)$
(c) $\text{WO}_3(s) + 3\,\text{H}_2(g) \longrightarrow \text{W}(s) + 3\,\text{H}_2\text{O}(g)$
(d) $4\,\text{NH}_2\text{OH}(l) + \text{O}_2(g) \longrightarrow 6\,\text{H}_2\text{O}(l) + 2\,\text{N}_2(g)$
(e) $\text{Al}_4\text{C}_3(s) + 12\,\text{H}_2\text{O}(l) \longrightarrow 4\,\text{Al(OH)}_3(s) + 3\,\text{CH}_4(g)$

22.19 (a) ${}^{1}_{1}$H, protium; ${}^{2}_{1}$H, deuterium; ${}^{3}_{1}$H, tritium (b) in order of decreasing natural abundance: protium $>$ deuterium $>$ tritium (c) Tritium is radioactive. (d) ${}^{3}_{1}\text{H} \longrightarrow {}^{3}_{2}\text{He} + {}^{0}_{-1}\text{e}$ **22.21** Like other elements in group 1A, hydrogen has only one valence electron and its most common oxidation number is $+1$.

22.23 (a) $\text{Mg}(s) + 2\,\text{H}^+(aq) \longrightarrow \text{Mg}^{2+}(aq) + \text{H}_2(g)$
(b) $\text{C}(s) + \text{H}_2\text{O}(g) \xrightarrow{1100\,^\circ\text{C}} \text{CO}(g) + 3\,\text{H}_2(g)$
(c) $\text{CH}_4(g) + \text{H}_2\text{O}(g) \xrightarrow{1100\,^\circ\text{C}} \text{CO}(g) + 3\,\text{H}_2(g)$

22.25 (a) $\text{NaH}(s) + \text{H}_2\text{O}(l) \longrightarrow \text{NaOH}(aq) + \text{H}_2(g)$
(b) $\text{Fe}(s) + \text{H}_2\text{SO}_4(aq) \longrightarrow \text{Fe}^{2+}(aq) + \text{H}_2(g) + \text{SO}_4^{\,2-}(aq)$
(c) $\text{H}_2(g) + \text{Br}_2(g) \longrightarrow 2\,\text{HBr}(g)$
(d) $2\,\text{Na}(l) + \text{H}_2(g) \longrightarrow 2\,\text{NaH}(s)$
(e) $\text{PbO}(s) + \text{H}_2(g) \xrightarrow{\Delta} \text{Pb}(s) + \text{H}_2\text{O}(g)$ **22.27** (a) Ionic (b) molecular (c) metallic **22.29** Vehicle fuels produce energy via combustion reactions. The combustion of hydrogen is very exothermic and its only product, H_2O, is a non-pollutant. **22.31** Xenon has a lower ionization energy than argon; because the valence electrons are not as strongly attracted to the nucleus, they are more readily promoted to a state in which the atom can form bonds with fluorine. Also, Xe is larger and can more easily accommodate an expanded octet of electrons.

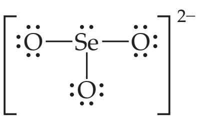
22.33 (a) Ca(OBr)_2, Br, $+1$ (b) HBrO_3, Br, $+5$ (c) XeO_3, Xe, $+6$ (d) $\text{ClO}_4^{\,-}$, Cl, $+7$ (e) HIO_2, I, $+3$ (f) IF_5; I, $+5$; F, -1 **22.35** (a) iron(III) chlorate, Cl, $+5$; (b) chlorous acid, Cl, $+3$ (c) xenon hexafluoride, F, -1 (d) bromine pentafluoride; Br, $+5$; F, -1 (e) xenon oxide tetrafluoride, F, -1 (f) iodic acid, I, $+5$; **22.37** (a) van der Waals intermolecular attractive forces increase with increasing number of electrons in the atoms. (b) F_2 reacts with water: $\text{F}_2(g) + \text{H}_2\text{O}(l) \longrightarrow 2\,\text{HF}(g) + \text{O}_2(g)$. That is, fluorine is too strong an oxidizing agent to exist in water. (c) HF has extensive hydrogen bonding. (d) Oxidizing power is related to electronegativity. Electronegativity and oxidizing power decrease in the order given.

22.39 (a) $2\,\text{HgO}(s) \xrightarrow{\Delta} 2\,\text{Hg}(l) + \text{O}_2(g)$
(b) $2\,\text{Cu(NO}_3)_2(s) \xrightarrow{\Delta} 2\,\text{CuO}(s) + 4\,\text{NO}_2(g) + \text{O}_2(g)$
(c) $\text{PbS}(s) + 4\,\text{O}_3(g) \longrightarrow \text{PbSO}_4(s) + 4\,\text{O}_2(g)$
(d) $2\,\text{ZnS}(s) + 3\,\text{O}_2(g) \longrightarrow 2\,\text{ZnO}(s) + 2\,\text{SO}_2(g)$
(e) $2\,\text{K}_2\text{O}_2(s) + 2\,\text{CO}_2(g) \longrightarrow 2\,\text{K}_2\text{CO}_3(s) + \text{O}_2(g)$
(f) $3\,\text{O}_2(g) \xrightarrow{h\nu} 2\,\text{O}_3(g)$ **22.41** (a) acidic (b) acidic (c) amphoteric (d) basic **22.43** (a) H_2SeO_3, Se, $+4$ (b) KHSO_3, S, $+4$ (c) H_2Te, Te, -2 (d) CS_2, S, -2 (e) CaSO_4, S, $+6$ (f) CdS, S, -2 (g) ZnTe, Te, -2

22.45 (a)
$2\,\text{Fe}^{3+}(aq) + \text{H}_2\text{S}(aq) \longrightarrow 2\,\text{Fe}^{2+}(aq) + \text{S}(s) + 2\,\text{H}^+(aq)$
(b) $\text{Br}_2(l) + \text{H}_2\text{S}(aq) \longrightarrow 2\,\text{Br}^-(aq) + \text{S}(s) + 2\,\text{H}^+(aq)$
(c) $2\,\text{MnO}_4^{\,-}(aq) + 6\,\text{H}^+(aq) + 5\,\text{H}_2\text{S}(aq) \longrightarrow 2\,\text{Mn}^{2+}(aq) + 5\,\text{S}(s) + 8\,\text{H}_2\text{O}(l)$ (d) $2\,\text{NO}_3^{\,-}(aq) + \text{H}_2\text{S}(aq) + 2\,\text{H}^+(aq) \longrightarrow 2\,\text{NO}_2(aq) + \text{S}(s) + 2\,\text{H}_2\text{O}(l)$

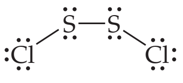
22.47

(a)



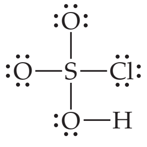
Trigonal pyramidal

(b)



Bent (free rotation around S–S bond)

(c)



Tetrahedral (around S)

22.49 (a) $SO_2(s) + H_2O(l) \rightleftharpoons H_2SO_3(aq) \rightleftharpoons H^+(aq) + HSO_3^-(aq)$
(b) $ZnS(s) + 2\,HCl(aq) \longrightarrow ZnCl_2(aq) + H_2S(g)$
(c) $8\,SO_3^{2-}(aq) + S_8(s) \longrightarrow 8\,S_2O_3^{2-}(aq)$
(d) $SO_3(aq) + H_2SO_4(l) \longrightarrow H_2S_2O_7(l)$ **22.51** (a) $NaNO_2$, +3 (b) NH_3, −3 (c) N_2O, + 1 (d) NaCN, −3 (e) HNO_3, +5 (f) NO_2, +4 (g) N_2, 0 (h) BN, −3

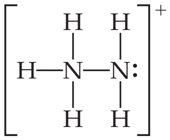
22.53 (a)

The molecule is bent around the central oxygen and nitrogen atoms; the four atoms need not be coplanar. The right-most form does not minimize formal charges and is less important in the actual bonding model. The oxidation state of N is +3.

(b)

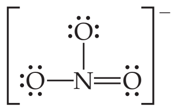
The molecule is linear. The oxidation state of N is −1/3.

(c)



The geometry is tetrahedral around the left nitrogen, trigonal pyramidal around the right. The oxidation state of N is −2.

(d)

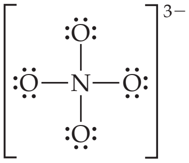


The ion is trigonal planar; it has three equivalent resonance forms. The oxidation state of N is +5.

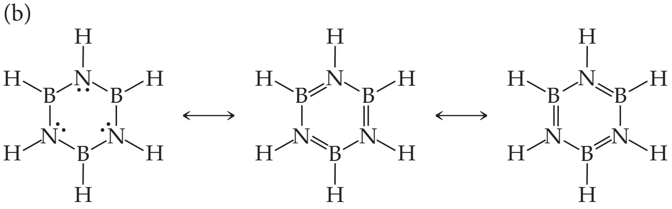
22.55 (a) $Mg_3N_2(s) + 6\,H_2O(l) \longrightarrow 3\,Mg(OH)_2(s) + 2\,NH_3(aq)$
(b) $2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g)$, redox reaction
(c) $N_2O_5(g) + H_2O(l) \longrightarrow 2\,H^+(aq) + 2\,NO_3^-(aq)$
(d) $NH_3(aq) + H^+(aq) \longrightarrow NH_4^+(aq)$
(e) $N_2H_4(l) + O_2(g) \longrightarrow N_2(g) + 2\,H_2O(g)$, redox reaction

22.57 (a) $HNO_2(aq) + H_2O(l) \longrightarrow NO_3^-(aq) + 2\,e^-$
(b) $N_2(g) + H_2O(l) \longrightarrow N_2O(aq) + 2\,H^+(aq) + 2\,e^-$

22.59 (a) H_3PO_3, +3 (b) $H_4P_2O_7$, +5 (c) $SbCl_3$, +3 (d) Mg_3As_2, +5 (e) P_2O_5, +5 (f) Na_3PO_4, +5 **22.61** (a) Phosphorus is a larger atom than nitrogen, and P has energetically available 3*d* orbitals, which participate in the bonding, but nitrogen does not. (b) Only one of the three hydrogens in H_3PO_2 is bonded to oxygen. The other two are bonded directly to phosphorus and are not easily ionized. (c) PH_3 is a weaker base than H_2O so any attempt to add H^+ to PH_3 in the presence of H_2O causes protonation of H_2O. (d) The P_4 molecules in white phosphorus have more severely strained bond angles than the chains in red phosphorus, causing white phosphorus to be more reactive. **22.63** (a) $2\,Ca_3PO_4(s) + 6\,SiO_2(s) + 10\,C(s) \longrightarrow$
$P_4(g) + 6\,CaSiO_3(l) + 10\,CO(g)$
(b) $PBr_3(l) + 3\,H_2O(l) \longrightarrow H_3PO_3(aq) + 3\,HBr(aq)$
(c) $4\,PBr_3(g) + 6\,H_2(g) \longrightarrow P_4(g) + 12\,HBr(g)$
22.65 (a) HCN (b) $Ni(CO)_4$ (c) $Ba(HCO_3)_2$ (d) CaC_2 (e) K_2CO_3 **22.67** (a) $ZnCO_3(s) \xrightarrow{\Delta} ZnO(s) + CO_2(g)$
(b) $BaC_2(s) + 2\,H_2O(l) \longrightarrow Ba^{2+}(aq) + 2\,OH^-(aq) + C_2H_2(g)$
(c) $2\,C_2H_2(g) + 5\,O_2(g) \longrightarrow 4\,CO_2(g) + 2\,H_2O(g)$
(d) $CS_2(g) + 3\,O_2(g) \longrightarrow CO_2(g) + 2\,SO_2(g)$
(e) $Ca(CN)_2(s) + 2\,HBr(aq) \longrightarrow CaBr_2(aq) + 2\,HCN(aq)$
22.69
(a) $2\,CH_4(g) + 2\,NH_3(g) + 3\,O_2(g) \xrightarrow{800^\circ C} 2\,HCN(g) + 6\,H_2O(g)$
(b) $NaHCO_3(s) + H^+(aq) \longrightarrow CO_2(g) + H_2O(l) + Na^+(aq)$
(c) $2\,BaCO_3(s) + O_2(g) + 2\,SO_2(g) \longrightarrow 2\,BaSO_4(s) + 2\,CO_2(g)$
22.71 (a) H_3BO_3, +3 (b) $SiBr_4$, +4 (c) $PbCl_2$, +2 (d) $Na_2B_4O_7 \cdot 10\,H_2O$, +3 (e) B_2O_3, + 3 (f) GeO_2, + 4
22.73 (a) Tin (b) carbon, silicon, and germanium (c) silicon
22.75 (a) Tetrahedral (b) Metasilicic acid will probably adopt the single-strand silicate chain structure shown in Figure 22.33 (b). The Si to O ratio is correct and there are two terminal O atoms per Si that can accommodate the two H atoms associated with each Si atom of the acid. **22.77** (a) Two Ca^{2+} (b) Two OH^- **22.79** (a) Diborane has bridging H atoms linking the two B atoms. The structure of ethane has the C atoms bound directly, with no bridging atoms. (b) B_2H_6 is an electron-deficient molecule. The 6 valence electron pairs are all involved in B—H sigma bonding, so the only way to satisfy the octet rule at B is to have the bridging H atoms shown in Figure 22.35. (c) The term *hydridic* indicates that the H atoms in B_2H_6 have more than the usual amount of electron density for a covalently bound H atom.
22.81 (a) False (b) true (c) false (d) true (e) true (f) true (g) false
22.84 (a) SO_3 (b) Cl_2O_5 (c) N_2O_3 (d) CO_2 (e) P_2O_5 **22.88** (a) PO_4^{3-}, +5; NO_3^-, +5, (b) The Lewis structure for NO_4^{3-} would be:



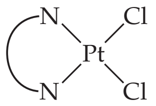
The formal charge on N is +1 and on each O atom is −1. The four electronegative oxygen atoms withdraw electron density, leaving the nitrogen deficient. Since N can form a maximum of four bonds, it cannot form a π bond with one or more of the O atoms to regain electron density, as the P atom in PO_4^{3-} does. Also, the short N—O distance would lead to a tight tetrahedron of O atoms subject to steric repulsion. **22.92** (a) 1.94×10^3 g H_2 (b) 2.16×10^4 L H_2 (c) 2.76×10^5 kJ
22.94 (a) −285.83 kJ/mol H_2; −890.4 kJ/mol CH_4
(b) −141.79 kJ/g H_2; −55.50 kJ/g CH_4 (c) 1.276×10^4 kJ/m^3 H_2; 3.975×10^4 kJ/m^3 CH_4 **22.96** (a) $[HClO] = 0.036M$ (b) pH = 1.4
22.99 (a) $SO_2(g) + 2\,H_2S(aq) \longrightarrow 3\,S(s) + 2\,H_2O(l)$ or
$8\,SO_2(g) + 16\,H_2S(aq) \longrightarrow 3\,S_8(s) + 16\,H_2O(l)$
(b) 4.0×10^3 mol = 9.7×10^4 L H_2S (c) 1.9×10^5 g S produced
22.101 The average bond enthalpies are H—O, 463 kJ; H—S, 367 kJ; H—Se, 316 kJ; H—Te, 266 kJ. The H—X bond enthalpy decreases steadily in the series. The origin of this effect is probably the increasing size of the orbital from X with which the hydrogen 1*s* orbital must overlap. **22.105** Dimethylhydrazine produces 0.0369 mol gas per gram of reactants, while methylhydrazine produces 0.0388 mol gas per gram of reactants. Methylhydrazine has marginally greater thrust.
2.107 (a)
$3\,B_2H_6(g) + 6\,NH_3(g) \longrightarrow 2\,(BH)_3(NH)_3(l) + 12\,H_2(g)$;
$3\,LiBH_4(s) + 3\,NH_4Cl(s) \longrightarrow 2\,(BH)_3(NH)_3(l) + 9\,H_2(g) + 3\,LiCl(s)$
(b)



(c) 2.40 g $(BH)_3(NH)_3$

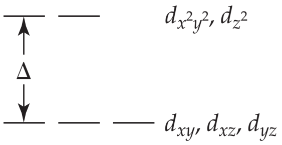
Chapter 23

23.2

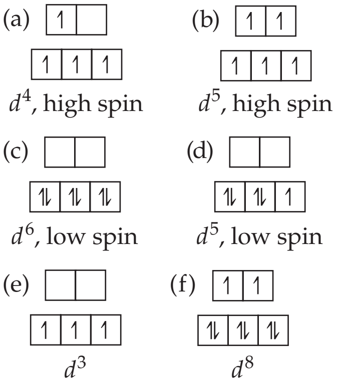


(a) Coordination number is 4 (b) coordination geometry is square planar (c) oxidation state is +2. **23.6** Molecules (1), (3), and (4) are chiral because their mirror images are not superimposable on the original molecules. **23.8** (a) Diagram (4) (b) diagram (1) (c) diagram (3) (d) diagram (2) **23.11** The lanthanide contraction explains trend (c). The lanthanide contraction is the name given to the decrease in atomic size due to the build-up in effective nuclear charge as we move through the lanthanides and beyond them. This effect offsets the expected increase in atomic size going from period 5 to period 6 transition elements. **23.13** (a) Ti^{2+}, $[Ar]3d^2$ (b) Ti^{4+}, $[Ar]$ (c) Ni^{2+}, $[Ar]3d^8$ (d) Zn^{2+}, $[Ar]3d^{10}$ **23.15** (a) Ti^{3+}, $[Ar]3d^1$ (b) Ru^{2+}, $[Kr]4d^6$ (c) Au^{3+}, $[Xe]4f^{14}5d^8$ (d) Mn^{4+}, $[Ar]3d^3$ **23.17** (a) The unpaired electrons in a paramagnetic material cause it to be weakly attracted into a magnetic field. **23.19** The diagram shows a material with misaligned spins that become aligned in the direction of an applied magnetic field. This is a paramagnetic material. **23.21** (a) Primary valence is roughly the same as oxidation number. Oxidation number is a broader term than ionic charge, but Werner's complexes contain metal ions where cation charge and oxidation number are equal. (b) Coordination number is the modern term for secondary valence. (c) NH_3 can serve as a ligand because it has an unshared electron pair, while BH_3 does not. Ligands are the Lewis base in metal–ligand interactions. As such, they must possess at least one unshared electron pair. **23.23** (a) +2 (b) 6 (c) 2 mol AgBr(s) will precipitate per mole of complex. **23.25** (a) Coordination number = 4, oxidation number = +2 (b) 5, +4 (c) 6, +3 (d) 5, +2 (e) 6, +3 (f) 4, +2 **23.27** (a) A monodentate ligand binds to a metal via one atom, a bidentate ligand binds through two atoms. (b) Three bidentate ligands fill the coordination sphere of a six-coordinate complex. (c) A tridentate ligand has at least three atoms with unshared electron pairs in the correct orientation to simultaneously bind one or more metal ions. **23.29** (a) *Ortho*-phenanthroline, *o*-phen, is bidentate (b) oxalate, $C_2O_4^{2-}$, is bidentate (c) ethylenediaminetetraacetate, EDTA, is pentadentate (d) ethylenediamine, en, is bidentate. **23.31** (a) The term chelate effect refers to the special stability associated with formation of a metal complex containing a polydentate (chelate) ligand relative to a complex containing only monodentate ligands. (b) The increase in entropy, $+\Delta S$ associated with the substitution of a chelating ligand for two or more monodentate ligands generally gives rise to the *chelate effect*. Chemical reactions with $+\Delta S$ tend to be spontaneous, have negative ΔG and large values of K. (c) Polydentate ligands are used as sequestering agents to bind metal ions and prevent them from undergoing unwanted chemical reactions without removing them from solution. **23.33** False. The ligand is not typically a bidentate ligand. The entire molecule is planar and the benzene rings on either side of the two N atoms inhibit their approach in the correct orientation for chelation. **23.35** (a) $[Cr(NH_3)_6](NO_3)_3$ (b) $[Co(NH_3)_4CO_3]_2SO_4$ (c) $[Pt(en)_2Cl_2]Br_2$ (d) $K[V(H_2O)_2Br_4]$ (e) $[Zn(en)_2][HgI_4]$ **23.37** (a) tetraamminedichlororhodium(III) chloride (b) potassium hexachlorotitanate(IV) (c) tetrachlorooxomolybdenum(VI) (d) tetraaqua(oxalato)platinum (IV) bromide **23.39** (a) Complexes 1, 2 and 3 can have geometric isomers; they each have cis-trans isomers. (b) Complex 2 can have linkage isomers, owing to the presence of the nitrite ligand. (c) The cis geometric isomer of complex 3 can have optical isomers (d) Complex 1 can have coordination sphere isomers. It is the only complex with a counter ion that can also be a ligand. **23.41** Yes. No structural or stereoisomers are possible for a tetrahedral complex of the form MA_2B_2. The complex must be square planar with cis and trans geometric isomers. **23.43** (a) One isomer (b) trans and cis isomers with 180° and 90° Cl—Ir—Cl angles, respectively (c) trans and cis isomers with 180° and 90° Cl—Fe—Cl angles, respectively. The cis isomer is optically active. **23.45** (a) Blue (b) $E = 3.26 \times 10^{-19}$ J/photon (c) $E = 196$ kJ/mol **23.47** (a) Diamagnetic. Zn^{2+}, $[Ar]3d^{10}$. There are no unpaired electrons. (b) Diamagnetic. Pd^{2+}, $[Kr]4d^8$. Square planar complexes with 8 d-electrons are usually diamagnetic, especially with a heavy metal center like Pd. (c) Paramagnetic. V^{3+}, $[Ar]3d^2$. The two *d*-electrons would be unpaired in any of the d-orbital energy level diagrams. **23.49** Most of the attraction between a metal ion and a ligand is electrostatic. Whether the interaction is ion–ion or ion–dipole, the ligand is strongly attracted to the metal center and can be modeled as a point negative charge.

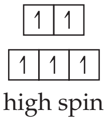
23.51 (a)



(b) The magnitude of Δ and the energy of the *d*-*d* transition for a d^1 complex are equal. (c) $\Delta = 220$ kJ/mol **23.53** (a) Cu^{2+}, $[Ar]3d^9$. Since the two minerals are colored, the copper ions in them must be in the +2 oxidation state. (b) Azurite will probably have the larger Δ. It absorbs orange visible light, which has shorter wavelengths than the red light absorbed by malachite. **23.55** (a) Ti^{3+}, d^1, (b) Co^{3+}, d^6 (c) Ru^{3+}, d^5 (d) Mo^{5+}, d^1 (e) Re^{3+}, d^4 **23.57** Yes. A weak-field ligand leads to a small Δ value and a small *d*-orbital splitting energy. If the splitting energy of a complex is smaller than the energy required to pair electrons in an orbital, the complex is high spin. **23.59** (a) Mn, $[Ar]4s^23d^5$; Mn^{2+}, $[Ar]3d^5$; 1 unpaired electron (b) Ru, $[Kr]5s^14d^7$; Ru^{2+}, $[Kr]4d^6$; 0 unpaired electrons (c) Rh, $[Kr]5s^14d^8$; Rh^{2+}, $[Kr]4d^7$; 1 unpaired electron **23.61** All complexes in this exercise are six-coordinate octahedral.

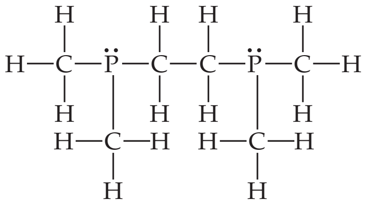


23.63

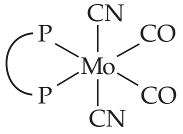


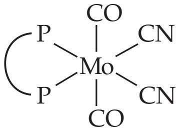
23.67 $[Pt(NH_3)_6]Cl_4$; $[Pt(NH_3)_4Cl_2]Cl_2$; $[Pt(NH_3)_3Cl_3]Cl$; $[Pt(NH_3)_2]Cl_4$; $K[Pt(NH_3)Cl_5]$

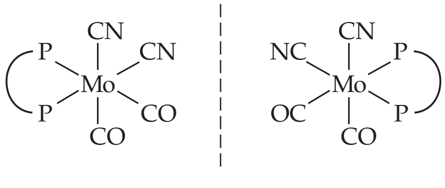
23.71



Both dmpe and en are bidentate ligands, binding through P and N, respectively. Because phosphorus is less electronegative than N, dmpe is a stronger electron pair donor and Lewis base than en. Dmpe creates a stronger ligand field and is higher on the spectrochemical series. Structurally, dmpe occupies a larger volume than en. M–P bonds are longer than M—N bonds and the two —CH_3 groups on each P atom in dmpe create more steric hindrance than the H atoms on N in en. (b) The oxidation state of Mo is zero. (c) The symbol $\overset{\frown}{P\,P}$ represents the bidentate dmpe ligand.

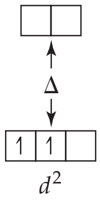






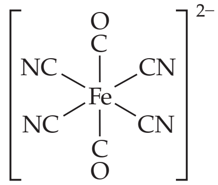
optical isomers

23.74 (a) Iron (b) magnesium (c) iron **23.76** (a) Pentacarbonyliron(0) (b) The oxidation state of iron must be zero. (c) Two. One isomer has CN in an axial position and the other has it in an equatorial position.
23.78 (a)



(b) These complexes are colored because the crystal-field splitting energy, Δ, is in the visible portion of the electromagnetic spectrum. Visible light with $\lambda = hc/\Delta$ is absorbed by the complex, promoting one of the *d*-electrons into a higher-energy *d*-orbital. The remaining wavelengths are reflected or transmitted; the combination of these wavelengths is the color we see. (c) $[V(H_2O)_6]^{3+}$ will absorb light with higher energy because it has a larger Δ than $[VF_6]^{3-}$. H_2O is in the middle of the spectrochemical series and causes a larger Δ than F^-, a weak-field ligand. **23.80** $[Co(NH_3)_6]^{3+}$, yellow; $[Co(H_2O)_6]^{2+}$, pink; $[CoCl_4]^{2-}$, blue

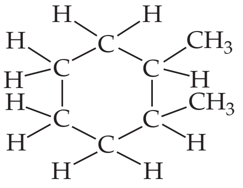
23.85 (a)



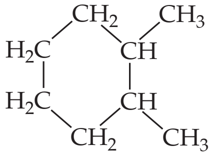
(b) sodium dicarbonyltetracyanoferrate(II) (c) +2, 6 *d*-electrons (d) We expect the complex to be low spin. Cyanide (and carbonyl) are high on the spectrochemical series, which means the complex will have a large Δ splitting, characteristic of low-spin complexes. **23.91** (a) Yes, the oxidation state of Co is +3 in both complexes. (b) Compound A has SO_4^{2-} outside the coordination sphere and coordinated Br^-, so it forms a precipitate with $BaCl_2(aq)$ but not $AgNO_3(aq)$. Compound B has Br^- outside the coordination sphere and coordinated SO_4^{2-}, so it forms a precipitate with $AgNO_3(aq)$ but not $BaCl_2(aq)$. (c) Compounds A and B are coordination sphere isomers. (d) Both compounds are strong electrolytes. **23.94** The chemical formula is $[Pd(NC_5H_5)_2Br_2]$. This is an electrically neutral square-planar complex of Pd(II), a nonelectrolyte whose solutions do not conduct electricity. Because the dipole moment is zero, it must be the trans isomer. **23.96** 47.3 mg Mg^{2+}/L, 53.4 mg Ca^{2+}/L **23.99** $\Delta E = 3.02 \times 10^{-19}$ J/photon, $\lambda = 657$ nm. The complex will absorb in the visible around 660 nm and appear blue-green.

Chapter 24

24.1 Molecules (c) and (d) are the same molecule. **24.7** (a) False (b) false (c) true (d) false **24.9** Numbering from the right on the condensed structural formula, C1 has trigonal-planar electron-domain geometry, 120° bond angles, and sp^2 hybridization; C2 and C5 have tetrahedral electron-domain geometry, 109° bond angles, and sp^3 hybridization; C3 and C4 have linear electron-domain geometry, 180° bond angles, and *sp* hybridization. **24.11** NH_3 and CO are not typical organic molecules. NH_3 contains no carbon atoms. Carbon monoxide contains a C atom that does not form four bonds. **24.13** (a) True (b) true (c) false (d) false (e) true (f) false (g) true **24.15** (a) 2-methylhexane (b) 4-ethyl-2,4-dimethyldecane (c) $CH_3CH_2CH_2CH_2CH_2CH(CH_3)_2$ (d) $CH_3CH_2CH_2CH_2CH(CH_2CH_3)CH(CH_3)CH(CH_3)_2$
(e)

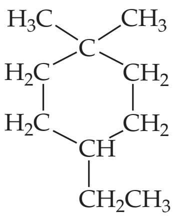


or



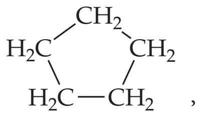
24.17 (a) 2,3-dimethylheptane (b) $CH_3CH_2CH_2C(CH_3)_3$

(c)



(d) 2,2,5-trimethylhexane (e) methylcyclobutane **24.19** 65
24.21 (a) Alkanes are said to be saturated because they cannot undergo addition reactions, such as those characteristic of carbon–carbon double bonds. (b) No. The compound C_4H_6 does not contain the maximum possible number of hydrogen atoms and is unsaturated.
24.23 (a) $CH_3CH_2CH_2CH_2CH_3$, C_5H_{12}

(b)

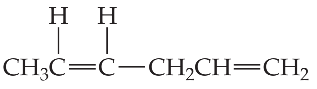


, C_5H_{10}

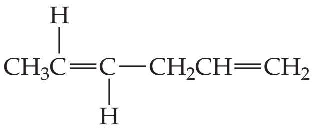
(c) $CH_2{=}CHCH_2\,CH_2\,CH_3$, $C_5\,H_{10}$
(d) $HC{\equiv}CCH_2CH_2CH_3$, C_5H_8 **24.25** One possible structure is $CH{\equiv}C{-}CH{=}CH{-}C{\equiv}CH$ **24.27** There are at least 46 structural isomers with the formula C_6H_{10}. A few of them are

$CH_3CH_2CH_2CH_2C{\equiv}CH$

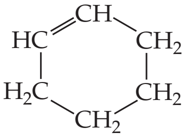
$CH_3CH_2CH_2C{\equiv}CCH_3$

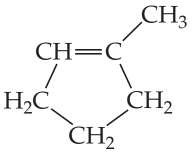


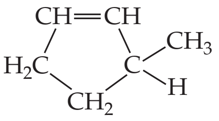
$$\mathrm{CH_3\overset{H}{\overset{|}{C}}{=}\overset{H}{\overset{|}{C}}{-}CH_2CH{=}CH_2}$$



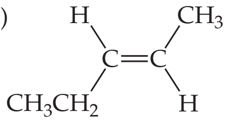
$$\mathrm{CH_3\overset{H}{\overset{|}{C}}{=}\underset{\underset{H}{|}}{C}{-}CH_2CH{=}CH_2}$$



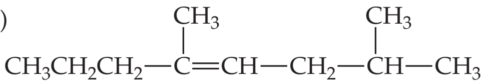




24.29 (a)



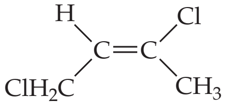
(b)

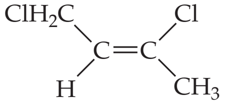


$$\mathrm{CH_3CH_2CH_2{-}\overset{CH_3}{\overset{|}{C}}{=}CH{-}CH_2{-}\overset{CH_3}{\overset{|}{CH}}{-}CH_3}$$

(c) *cis*-6-methyl-3-octene (d) *para*-dibromobenzene (e) 4,4-dimethyl-1-hexyne **24.31** (a) True (b) true (c) false **24.33** (a) No

(b)





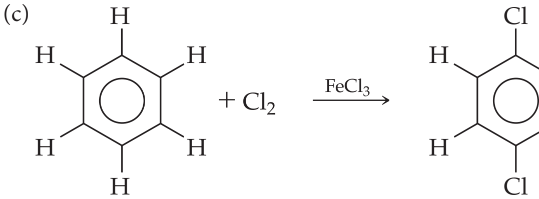
(c) no (d) no **24.35** (a) True

(b) $CH_3CH_2CH{=}CH{-}CH_3 + Br_2 \longrightarrow$
2-pentene

$CH_3CH_2CH(Br)CH(Br)CH_3$
2, 3-dibromopentane

This is an addition reaction.

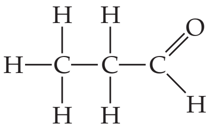
(c)



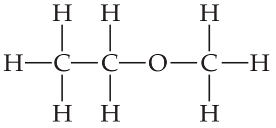
$C_6H_6 + Cl_2 \xrightarrow{FeCl_3} C_6H_4Cl_2$

This is an substitution reaction.

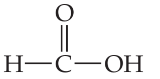
24.37 The 60° C—C—C angles in the cyclopropane ring cause strain that provides a driving force for reactions that result in ring opening. There is no comparable strain in the five-membered or six-membered rings. (b) $C_2H_4(g) + HBr(g) \longrightarrow CH_3CH_2Br(l)$; $C_6H_6(l) + CH_3CH_2Br(l) \xrightarrow{AlCl_3} C_6H_5CH_2CH_3(l) + HBr(g)$ **24.39** Yes, this information suggests (but does not prove) that the reactions proceed in the same manner. That the two rate laws are first order in both reactants and second order overall indicates that the activated complex in the rate-determining step in each mechanism is bimolecular and contains one molecule of each reactant. This is usually an indication that the mechanisms are the same, but it does not rule out the possibility of different fast steps or a different order of elementary steps. **24.41** $\Delta H_{\text{comb}}/\text{mol } CH_2$ for cyclopropane = 696.3 kJ, for cyclopentane = 663.4 kJ. $\Delta H_{\text{comb}}/CH_2$ group for cyclopropane is greater because C_3H_6 contains a strained ring. When combustion occurs, the strain is relieved and the stored energy is released. **24.43** (a) (iii) (b) (i) (c) (ii) (d) (iv) (e) (v) **24.45** (a) Propionaldehyde (or propanal):



(b) ethylmethyl ether:

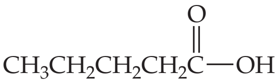


24.47 (a)



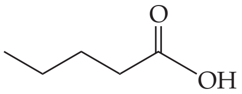
$\mathrm{H{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}OH}$

(b)

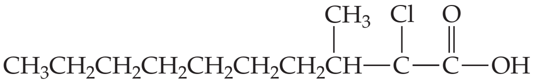


$\mathrm{CH_3CH_2CH_2CH_2\overset{\displaystyle O}{\overset{\|}{C}}{-}OH}$

or

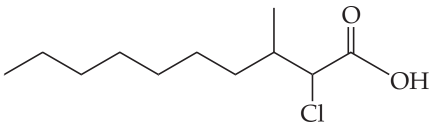


(c)

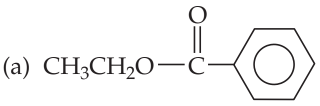


$\mathrm{CH_3CH_2CH_2CH_2CH_2CH_2CH_2\overset{\displaystyle CH_3}{\overset{|}{C}H}{-}\overset{\displaystyle Cl}{\overset{|}{C}}{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}OH}$

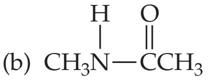
or



24.49

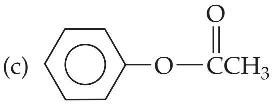


(a) Ethylbenzoate



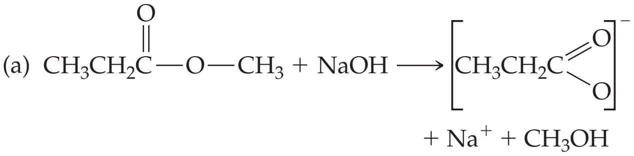
(b) $\mathrm{CH_3\overset{\displaystyle H}{\overset{|}{N}}{-}\overset{\displaystyle O}{\overset{\|}{C}}CH_3}$

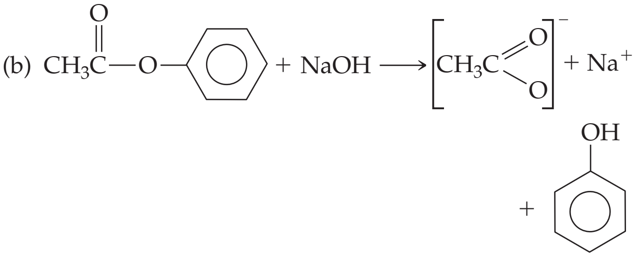
N-methylethanamide or
N-methylacetamide



(c) Phenylacetate

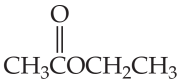
24.51





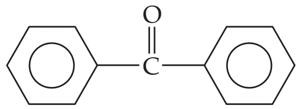
24.53 High melting and boiling points are indicators of strong intermolecular forces in the bulk substance. The presence of both —OH and —C=O groups in pure acetic acid leads us to conclude that it will be a strongly hydrogen-bonded substance. That the melting and boiling points of pure acetic acid are both higher than those of water, a substance we know to be strongly hydrogen-bonded, supports this conclusion. **24.55** (a) $CH_3CH_2CH_2CH(OH)CH_3$ (b) $CH_3CH(OH)CH_2OH$

(c)



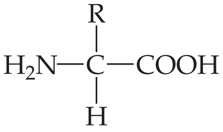
$\mathrm{CH_3\overset{\displaystyle O}{\overset{\|}{C}}OCH_2CH_3}$

(d)



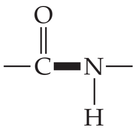
(e) $CH_3OCH_2CH_3$ **24.57** (c) There are two chiral carbon atoms in the molecule.

24.59 (a)

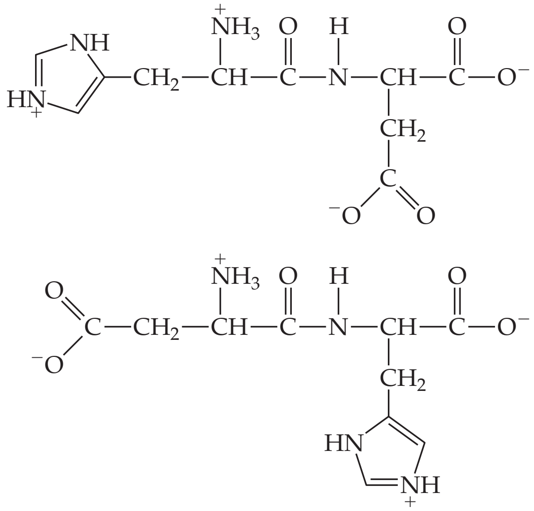


$\mathrm{H_2N{-}\overset{\displaystyle R}{\overset{|}{\underset{\displaystyle H}{\underset{|}{C}}}}{-}COOH}$

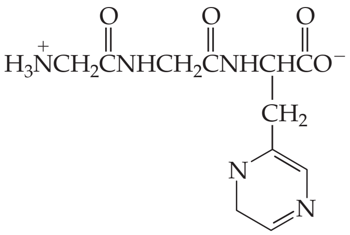
(b) In protein formation, amino acids undergo a condensation reaction between the amino group of one molecule and the carboxylic acid group of another to form the amide linkage. (c) The bond that links amino acids in proteins is called the peptide bond. It is shown in bold in the figure below.



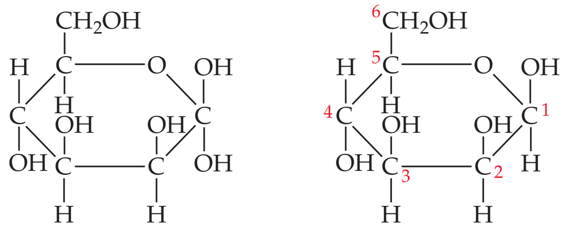
24.61



24.63 (a)

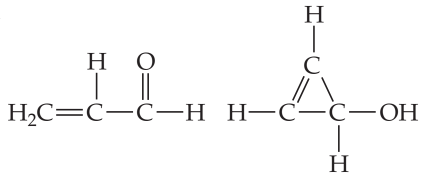


(b) Three tripeptides are possible: Gly-Gly-His, GGH; Gly-His-Gly, GHG; His-Gly-Gly, HGG **24.65** (a) True (b) false (c) false **24.67** (a) True (b) false (c) true **24.69** (a) The empirical formula of cellulose is $C_6H_{10}O_5$. (b) The six-membered ring form of glucose is the monomer unit that is the basis of the polymer cellulose. (c) Ether linkages connect the glucose monomer units in cellulose. **24.71** (a) Yes. (b) Four. In the linear form of mannose, the aldehydic carbon is C1. Carbon atoms 2, 3, 4, and 5 are chiral because they each carry four different groups. (c) Both the α (left) and β (right) forms are possible.



24.73 (a) False (b) true (c) true **24.75** *Purines*, with the larger electron cloud and molar mass, will have larger dispersion forces than *pyrimidines* in aqueous solution. **24.77** 5′−TACG−3′ **24.79** The complimentary strand for 5′−GCATTGGC−3′ is 3′−CGTAACCG−5′.

24.81



24.90 (a) None (b) The carbon bearing the secondary —OH has four different groups attached, and is thus chiral. (c) The carbon bearing the —NH_2 group and the carbon bearing the CH_3 group are both chiral. **24.95** In both cases, stronger intermolecular forces lead to the higher boiling point. Ethanol contains O—H bonds, which form strong intermolecular hydrogen bonds, while dimethyl ether experiences only weak dipole–dipole and dispersion forces. The heavier and polar CH_2F_2 experiences dipole–dipole and stronger dispersion forces, while CH_4 experiences only weaker dispersion forces. **24.99** $\Delta G^\circ = 13$ kJ

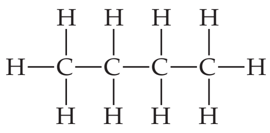
ANSWERS TO GIVE IT SOME THOUGHT

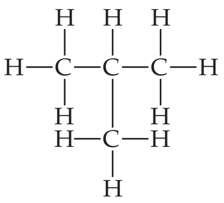
Chapter 1

page 5 (a) 100 (b) atoms ***page 10*** Water is composed of two types of atoms: hydrogen and oxygen. Hydrogen is composed only of hydrogen atoms, and oxygen is composed only of oxygen atoms. Therefore, hydrogen and oxygen are elements and water is a compound. ***page 12*** Density is an intensive property. Because it is measured per unit of volume, it is independent of how much of the material is present. ***page 13*** (a) Chemical change: Carbon dioxide and water are different compounds than sugar. (b) Physical change: Water in the gas phase becomes water in the solid phase (frost). (c) Physical change: Gold in the solid state becomes liquid and then resolidifies. ***page 16*** The candela, cd. ***page 19*** 10^3 ***page 19*** $2.5 \times 10^2\ m^3$ is, because it has units of length to the third power. ***page 22*** (b) Mass of a penny ***page 23*** 154.9 ± 0.1 lbs. The average deviation is about 0.1 lb ***page 25*** the 18 m measurement needs to be made to greater accuracy, so that is also has three significant figures ***page 28*** Use all digits given in the conversion factor. Conversion factors may be exact and then have “infinite” significant digits (for example, 2.54 cm = 1 inch exactly). Usually, your answer will have its number of significant digits limited by those of the quantities given in the problem.

Chapter 2

page 43 (a) The law of multiple proportions. (b) The second compound must contain two oxygen atoms for each carbon atom (that is, twice as many carbon atoms as the first compound). ***page 44*** This observation shows that the cathode rays are comprised of the same entity present in all the elements used as cathode, not something characteristic of the individual elements. ***page 47*** Most α particles pass through the foil without being deflected because most of the volume of the atoms that comprise the foil is empty space. ***page 48*** (a) The atom has 15 electrons because atoms have equal numbers of electrons and protons. (b) The protons reside in the nucleus of the atom. ***page 51*** Any single atom of chromium must be one of the isotopes of that element. The isotope mentioned has a mass of 52.94 amu and is probably ^{53}Cr. The atomic weight differs from the mass of any particular atom because it is the *average* atomic mass of the naturally occurring isotopes of the element. ***page 55*** (a) Cl, (b) third period and group 7A, (c) 17, (d) nonmetal ***page 56*** B_2H_6 and $C_4H_2O_2$ can be only molecular formulas; their empirical formulas would be BH_3 and C_2HO. SO_2 and CH could be empirical formulas or molecular formulas. No formula can be *only* an empirical formula; there could always be a molecule of that composition ***page 57*** (a) C_2H_6, (b) CH_3, (c) Probably the ball-and-stick model because the angles between the sticks indicate the angles between the atoms ***page 61*** No. The formula does not contain any information regarding the nature of the bonds between the constituent atoms. ***page 64*** (a) Chromium exhibits differing charges in its compounds, so we need to identify what charge it has in this case. In contrast, calcium is always 2+ in its compounds (b) It tells us that the ammonium ion is a cation; that is, positively charged. ***page 65*** The endings convey the number of oxygen atoms bound to the nonmetallic element ***page 65*** Borate by extension of Nitrate ⟶ Carbonate ⟶ should be BO_3^{3-}. Silicate should be SiO_4^{4-}. ***page 67*** (a) $CaHCO_3$, (b) $KHSO_4$, LiH_2PO_4 ***page 68*** Iodic acid, by analogy to the relationship between the chlorate ion and chloric acid ***page 69*** No, it contains three different elements. ***page 70***





Chapter 3

page 82 Each $Mg(OH)_2$ has 1 Mg, 2 O, and 2 H; thus, 3 $Mg(OH)_2$ represents 3 Mg, 6 O, and 6 H. ***page 88*** The product is an ionic compound involving Na^+ and S^{2-}, and its chemical formula is therefore Na_2S. ***page 94*** (a) A mole of glucose. By inspecting their chemical formulas we find that glucose has more atoms of H and O than water and in addition it also has C atoms. Thus, a molecule of glucose has a greater mass than a molecule of water. (b) They both contain the same number of molecules because a mole of each substance contains 6.02×10^{23} molecules. ***page 99*** No, chemical analysis cannot distinguish compounds that have different molecular formulas but the same empirical formula. ***page 102*** There are experimental uncertainties in the measurements. ***page 103*** 3.14 mol because 2 mol $H_2 \cong$ 1 mol O_2 based on the coefficients in the balanced equation ***page 104*** Two mol of H_2 are consumed for every mol of O_2 that reacts, so 3.14 mol H_2 would be consumed. ***page 105*** To obey the law of conservation of mass the mass of the products consumed must equal the mass of reactants formed, therefore the mass of H_2O produced is $1.00\ g + 3.59\ g - 3.03\ g = 1.56\ g\ H_2O$.

Chapter 4

page 126 (a) $K^+(aq)$ and $CN^-(aq)$ (b) $Na^+(aq)$ and $ClO_4^-(aq)$ ***page 127*** NaOH because it is the only solute that is a strong electrolyte ***page 131*** $Na^+(aq)$ and $NO_3^-(aq)$ ***page 133*** Three. Each COOH group will partially ionize in water to form $H^+(aq)$. ***page 134*** Only soluble metal hydroxides are classified as strong bases and $Al(OH)_3$ is insoluble. ***page 138*** $SO_2(g)$ ***page 141*** (a) -3, (b) $+5$ ***page 144*** (a) Yes, nickel is below zinc in the activity series so $Ni^{2+}(aq)$ will oxidize $Zn(s)$ to form $Ni(s)$ and $Zn^{2+}(aq)$. (b) No reaction will occur because the $Zn^{2+}(aq)$ ions cannot be further oxidized. ***page 146*** The second solution is more concentrated, 2.50 *M*, than the first solution, which has a concentration of 1.00 *M*. ***page 150*** The concentration is halved to 0.25 *M*.

Chapter 5

page 168 (a) No. The potential energy is lower at the bottom of the hill. (b) Once the bike comes to a stop, its kinetic energy is zero, just as it was at the top of the hill. ***page 169*** Open system. Humans exchange matter and energy with their surroundings. ***page 173*** Endothermic ***page 175*** The balance (current state) does not depend on the ways the money may have been transferred into the account or on the particular expenditures made in withdrawing money from the account. It depends only on the net total of all the transactions. ***page 176*** No. If ΔV is zero, then the expression $w = -P\Delta V$ is also zero. ***page 177*** ΔH is positive; the fact that the flask (part of the surroundings) gets cold means that the system is absorbing heat, meaning that q_P is positive. (See Figure 5.8.) Because the process occurs at constant pressure, $q_p = \Delta H$. ***page 179*** No. Because only half as much matter is involved, the value of ΔH would be $\frac{1}{2}(-483.6\ kJ) = -241.8\ kJ$. ***page 182*** $Hg(l)$. Rearranging Equation 5.22 gives $\Delta T = \dfrac{q}{C_s \times m}$. When q and m are constant for a series of substances, then $\Delta T = \dfrac{\text{constant}}{C_s}$. Therefore, the element with the smallest C_s in Table 5.2 has the largest ΔT, $Hg(l)$. ***page 187*** (a) The sign of ΔH changes. (b) The magnitude of ΔH doubles. ***page 191*** No. Because $O_3(g)$ is not the most stable form of oxygen at 25 °C, 1 atm $[O_2(g)$ is$]$, ΔH_f° for $O_3(g)$ is not necessarily zero. In Appendix C we see that it is 142.3 kJ/mol. ***page 196*** Fats, because they have the largest fuel value of the three

Chapter 6

page 214 No. Both visible light and X-rays are forms of electromagnetic radiation. They therefore both travel at the speed of light, *c*. Their differing ability to penetrate skin is due to their different energies, which we will discuss in the next section. ***page 217*** The notes on a piano go in "jumps"; for example, one can't play a note between B and C on a piano. In this analogy, a violin is continuous—in principle, one can play any note (such as a note halfway between B and C). ***page 218*** No. The energy of the emitted electron will equal the energy of the photon minus the work function. ***page 219*** Wave-like behavior. ***page 220*** The energies in the Bohr model have only certain specific allowed values, much like the positions on the steps in Figure 6.6. ***page 221*** A larger orbit means the electron is farther from the nucleus and therefore experiences less attraction. Thus, the energy is higher. ***page 222*** ΔE is negative for an emission. The negative sign yields a positive number that corresponds to the energy of the emitted photon. ***page 222*** This will be an absorption so $1/\lambda = \Delta E/hc$. ***page 224*** Yes, all moving objects produce matter waves, but the wavelengths associated with macroscopic objects, such as the baseball, are too small to allow for any way of observing them. ***page 226*** The small size and mass of subatomic particles. The term $h/4\pi$ in the uncertainty principle is a very small number that becomes important only when considering extremely small objects, such as electrons. ***page 227*** In the first statement, we know exactly where the electron is. In the second statement, we are saying that we know the probability of the electron being at a point, but we don't know exactly where it is. The second statement is consistent with the Uncertainty Principle. ***page 228*** Bohr proposed that the electron in the hydrogen atom moves in a well-defined circular path around the nucleus (an orbit). In the quantum-mechanical model, the motion of the electron is not well-defined and we must use a probabilistic description. An orbital is a wave function related to the probability of finding the electron at any point in space. ***page 230*** The energy of an electron in the hydrogen atom is proportional to $-1/n^2$, as seen in Equation 6.5. The difference between $-1/(2)^2$ and $-1/(1)^2$ is much greater than the difference between $-1/(3)^2$ and $-1/(2)^2$. ***page 235*** No. Based on what we have learned, all we know is that both the 4*s* and 3*d* orbitals are higher in energy than the 3*s* orbital. In most atoms, the 4*s* is actually lower in energy than the 3*d*, as shown in Figure 6.25. ***page 240*** The 6*s* orbital, which starts to hold electrons at element 55, Cs. ***page 245*** We can't conclude anything! Each of the three elements has a different valence electron configuration for its $(n - 1)d$ and ns subshells: For Ni, $3d^8 4s^2$; for Pd, $4d^{10}$; and for Pt, $5d^9 6s^1$.

Chapter 7

page 259 Co and Ni and Te and I are other pairs of elements whose atomic weights are out of order compared to their atomic numbers. ***page 262*** The 2*p* electron in a Ne atom would experience a larger Z_{eff} than the 3*s* electron in Na, due to the greater shielding of the 3*s* electron of the Na atom by all the 2*s* and 2*p* electrons. ***page 264*** These trends work against each other: Z_{eff} increasing would imply that the valence electrons are pulled tighter in to make the atom smaller, while orbital size "increasing" would imply that atomic size would also increase. The orbital size effect is larger: As you go down a column in the periodic table, atomic size generally increases. ***page 268*** It is harder to remove another electron from Na^+, so the process in Equation 7.3 would require more energy and, hence, shorter-wavelength light (see Sections 6.1 and 6.2). ***page 269*** I_2 for a carbon atom corresponds to ionizing an electron from C^+, which has the same number of electrons as a neutral B atom. Z_{eff} will be greater for C^+ than for B, so I_2 for a carbon atom will be greater than I_1 for a boron atom. ***page 271*** The same. ***page 273*** The magnitudes are the same, but they have opposite signs. ***page 274*** No. The oxidation state of As will be positive when combined with Cl, and negative when combined with Mg. ***page 277*** Because the melting point is so low, we would expect a molecular rather than ionic compound. Thus, A is more likely to be P than Sc because PCl_3 is a compound of two nonmetals and is therefore more likely to be molecular. ***page 280*** Its low first ionization energy. ***page 282*** In the acidic environment of the stomach, metal carbonates can react to give carbonic acid, which decomposes to water and carbon dioxide gas. Thus, calcium carbonate is much more soluble in acidic solution than it is in neutral water. ***page 284*** The longest wavelength of visible light is about 750 nm (Section 6.1). We can assume that this corresponds to the lowest energy of light (since $E = hc/\lambda$) needed to break bonds in hydrogen peroxide. If we plug in 750 nm forλ, we can calculate the minimum energy to break one O—O bond in one molecule of hydrogen peroxide, in joules. If we multiple by Avogadro's number, we can calculate how many joules it would take to break a mole of O—O bonds in hydrogen peroxide (which is the number one normally finds). ***page 285*** The halogens all have ground-state electron configurations that are ns^2np^5; sharing an electron with only one other atom generally makes a stable compound. ***page 286*** Based on the trends in the table, we might expect the radius to be about 1.5 Å, and the first ionization energy to be about 900 kJ/mol. In fact, its bonding radius is indeed 1.5 Å, and the experimental ionization energy is 920 kJ/mol.

Chapter 8

page 300 No. Cl has seven valence electrons. The first and second Lewis symbols are both correct—they both show seven valence electrons, and it doesn't matter which of the four sides has the single electron. The third symbol shows only five electrons and is incorrect. ***page 302*** CaF_2 is an ionic compound consisting of Ca^{2+} and F^- ions. When Ca and F_2 react to form CaF_2, each Ca atom loses two electrons to form a Ca^{2+} ion and each fluorine atom in F_2 takes up an electron, forming two F^- ions. Thus, we can say that each Ca atom transfers one electron to each of two fluorine atoms. ***page 303*** No. This reaction corresponds to the lattice energy for KCl, which is a large positive number. Therefore, the reaction will cost energy, not release energy. ***page 306*** Rhodium, Rh ***page 307*** Weaker. In both H_2 and $H_2{}^+$ the two H atoms are principally held together by the electrostatic attractions between the nuclei and the electron(s) concentrated between them. $H_2{}^+$ has only one electron between the nuclei whereas H_2 has two and this results in the H — H bond in H_2 being stronger. ***page 309*** Triple bond. CO_2 has two C—O double bonds. Because the C—O bond in carbon monoxide is shorter, it is likely to be a triple bond. ***page 309*** Electron affinity measures the energy released when an isolated atom gains an electron to form a 1− ion and has units of energy. Electronegativity has no units, and is the ability of the atom in a molecule to attract electrons to itself within that molecule. ***page 311*** Polar covalent. The difference in electronegativity between S and O is $3.5 - 2.5 = 1.0$. Based on the examples of F_2, HF, and LiF, the difference in electronegativity is great enough to introduce some polarity to the bond but not sufficient to cause a complete electron transfer from one atom to the other. ***page 312*** IF. Because the difference in electronegativity between I and F is greater than that between Cl and F, the magnitude of Q should be greater for IF. In addition, because I has a larger atomic radius than Cl, the bond length in IF is longer than that in ClF. Thus, both Q and *r* are larger for IF and, therefore, $\mu = Qr$ will be larger for IF. ***page 313*** Smaller dipole moment for C—H The magnitude of Q should be similar for C—H and H—I bonds because the difference in electronegativity for each bond is 0.4. The C—H bond length is 1.1 Å and the H—I bond length is 1.6 Å. Therefore $\mu = Qr$ will be greater for H—I because it has a longer bond (larger *r*). ***page 315*** OsO_4. The data suggest that the yellow substance is a molecular species with its low melting and boiling points. Os in OsO_4 has an oxidation number of +8 and Cr in Cr_2O_3 has an oxidation number of +3. In Section 8.4, we learn that a compound with a metal in a high oxidation state should show a high degree of covalence and OsO_4 fits this situation. ***page 318*** There is probably a better choice of Lewis structure than the one chosen. Because the formal charges must add up to 0 and the formal charge on the F atom is +1, there must be another atom that has a formal charge of −1. Because F is the most electronegative element, we don't expect it to carry a positive formal charge. ***page 320*** Yes. There are two resonance structures for ozone that each contribute equally to the overall description of the molecule. Each O—O bond is therefore an average of a single bond and a double bond, which is a "one-and-a-half" bond. ***page 321*** As "one-and-a-third" bonds. There are three resonance structures, and each of the three N—O bonds is single in two of those structures and double in the third. Each bond in the actual ion is an average of these: $(1 + 1 + 2)/3 = 1\frac{1}{3}$. ***page 322*** No, it will not have multiple resonance structures. We can't "move" the double bonds, as we did in benzene, because the positions of the hydrogen atoms dictate specific positions for the double bonds. We can't write any other reasonable Lewis structures for the molecule. ***page 323*** The formal charge of each atom is shown here:

The first structure shows each atom with a zero formal charge and therefore it is the dominant Lewis structure. The second one shows a positive formal charge for an oxygen atom, which is a highly electronegative atom, and this is not a favorable situation. ***page 326*** The atomization of ethane produces $2\ C(g) + 6\ H(g)$. In this process, six C—H bonds and one C—C bond are broken. We can use $6D(C—H)$ to estimate the amount of enthalpy needed to break the six C—H bonds. The difference between that number and the enthalpy of atomization is an estimate of the bond enthalpy of the C—C bond, $D(C—C)$. ***page 327*** H_2O_2. From Table 8.4, the bond enthalpy of the O—O single bond in H_2O_2 (146 kJ/mol) is much lower than that of the O═O bond in O_2(495 kJ/mol). The weaker bond in H_2O_2 is expected to make it more reactive than O_2.

Chapter 9

page 346 Removal of two opposite atoms from an octahedral arrangement would lead to square-planar shape. ***page 347*** No, the molecule does not satisfy the octet rule because there are ten electrons around the atom A. Each of the atoms B does satisfy the octet rule. There are four electron domains around A: Two single bonds, one double bond, and one nonbonding electron domain around A. ***page 349*** Each counts as a single electron domain around the central atom. ***page 352*** Yes. Because there are three equivalent dominant resonance structures, each of which puts the double bond between the N and a different O, the average structure has the same bond order for all three N—O bonds. Thus, each electron domain is the same and the angles are predicted to be 120°. ***page 352*** In a square planar arrangement of electron domains, each domain is 90° from two other domains (and 180° from the third domain). In a tetrahedral arrangement, each domain is 109.5° from the other three domains. Domains always try to minimize the number of 90° interactions, so the tetrahedral arrangement is favored. ***page 357*** No. Although the bond dipoles are in opposite directions, they will not have the same magnitude because the C—S bond is not as polar as the C—O bond. Thus, the sum of the two vectors will not equal zero and the molecule is polar. ***page 361*** They are both oriented perpendicular to the F—Be—F axis. ***page 362*** None. All of the 2*p* orbitals are used in constructing the sp^3 hybrid orbitals. ***page 367*** There are three electron domains about each N atom, so we expect sp^2 hybridization at each of the N atoms. The H—N—N angles should therefore be roughly 120°, and the molecule is not expected to be linear. In order for the π bond to form, all four atoms would have to be in the same plane. ***page 373*** *sp* hybridization. ***page 376*** The excited molecule would fall apart. It would have an electron configuration $\sigma_{1s}^1\sigma_{1s}^{\star 1}$ and therefore a bond order of 0. ***page 377*** Yes, it will have a bond order of $\frac{1}{2}$. ***page 383*** No. If the σ_{2p} MO were lower in energy than the π_{2p} MOs we would expect the last two electrons to go into the π_{2p} MOs with the same spin, which would cause C_2 to be paramagnetic.

Chapter 10

page 401 No. The heaviest gas in Table 10.1 is SO_2, whose molar mass, 64 g/mol, is less than half that of Xe, whose molar mass is 131 g/mol. ***page 402*** 1.4×10^3 lbs ***page 402*** (a) 745 mm Hg, (b) 0.980 atm, (c) 99.3 kPa, (d) 0.993 bar ***page 405*** It would be halved. ***page 406*** No because the absolute temperature is not halved, it only decreases from 373 K to 323 K. ***page 409*** 28.2 cm ***page 413*** Less dense because water has a smaller molar mass, 18 g/mol, than N_2, 28 g/mol. ***page 416*** The partial pressure of N_2 is not affected by the introduction of another gas, but the total pressure will increase. ***page 420*** Slowest $HCl < O_2 < H_2$ fastest. ***page 422*** $u_{rms}/u_{mp} = \sqrt{3/2}$. This ratio will not change as the temperature changes and it will be the same for all gases. ***page 426*** (a) Decrease, (b) have no effect. ***page 427*** (b) 100 K and 5 atm ***page 428*** The negative deviation is due to attractive intermolecular forces.

Chapter 11

page 446 $H_2O(g)$; during boiling, energy is provided to overcome intermolecular forces between H_2O molecules allowing the vapor to form. ***page 448*** $CH_4 < CCl_4 < CBr_4$. Because all three molecules are nonpolar, the strength of dispersion forces determines the relative boiling points. Polarizability increases in order of increasing molecular size and molecular weight, $CH_4 < CCl_4 < CBr_4$; hence, the dispersion forces and boiling points increase in the same order. ***page 452*** Mainly hydrogen bonds, which hold the individual H_2O molecules together in the liquid. ***page 452*** $Ca(NO_3)_2$ in water, because calcium nitrate is a strong electrolyte that forms ions and water is a polar molecule with a dipole moment. Ion–dipole forces cannot be present in a CH_3OH/H_2O mixture because CH_3OH does not form ions. ***page 456*** (a) Both viscosity and surface tension decrease with increasing temperature because of the increased molecular motion. (b) Both properties increase as the strength of intermolecular forces increases. ***page 459*** Melting (or fusion), endothermic ***page 461*** The intermolecular attractive forces in H_2O are much stronger than those in H_2S because H_2O can form hydrogen bonds, The stronger intermolecular forces results in a higher critical temperature and pressure. ***page 463*** CCl_4. Both compounds are nonpolar; therefore, only dispersion forces exist between the molecules. Because dispersion forces are stronger for the larger, heavier CBr_4, it has a lower vapor pressure than CCl_4. The substance with the larger vapor pressure at a given temperature is more volatile.

Chapter 12

page 484 Tetragonal. There are two three-dimensional lattices that have a square base with a third vector perpendicular to the base, tetragonal and cubic, but in a cubic lattice the *a*, *b*, and *c* lattice vectors are all of the same length. ***page 487*** Ionic solids are composed of ions. Oppositely-charged ions slipping past each other could create electrostatic repulsions, so ionic solids are brittle. ***page 491*** The packing efficiency decreases as the number of nearest neighbors decreases. The structures with the highest packing efficiency, hexagonal and cubic close packing, both have atoms with a coordination number of 12. Body-centered cubic packing, where the coordination number is 8, has a lower packing efficiency, and primitive cubic packing, where the coordination number is 6, has a lower packing efficiency still. ***page 492*** Interstitial, because boron is a small nonmetal atom that can fit in the voids between the larger palladium atoms ***page 498*** Gold, Au should have more electrons in antibonding orbitals. Tungsten, W, lies near the middle of the transition metal series where the bands arising from the d orbitals and the s orbital are approximately half-filled. This electron count should fill the bonding orbitals and leave the antibonding orbitals mostly empty. Because both elements have similar numbers of electrons in the bonding orbitals but tungsten has fewer electrons in antibonding orbitals, it will have a higher melting point. ***page 499*** No. In a crystal the lattice points must be identical. Therefore, if an atom lies on top of a lattice point, then the same type of atom must lie on all lattice points. In an ionic compound there are at least two different types of atoms, and only one can lie on the lattice points. ***page 501*** Four. The empirical formula of potassium oxide is K_2O. Rearranging Equation 12.1 we

can determine the potassium coordination number to be anion coordination number $\times$ (number of anions per formula unit/number of cations per formula unit) $= 8(1/2) = 4$. ***page 511*** A condensation polymer. The presence of both —COOH and —NH_2 groups allow molecules to react with one another forming C—N bonds and eliminating H_2O. ***page 512*** As the vinyl acetate content increases more side chain branching occurs which inhibits the formation of crystalline regions thereby lowering the melting point.
page 515 No. The emitted photons have energies that are similar in energy to the band gap of the semiconductor. If the size of the crystals is reduced into the nanometer range, the band gap will increase. However, because 340-nm light falls in the UV region of the electromagnetic spectrum, increasing the energy of the band gap will only shift the light deeper into the UV.

Chapter 13

page 532 Entropy increases as the ink molecules disperse into water. ***page 533*** The lattice energy of NaCl(s) must be overcome to separate Na^+ and Cl^- ions and disperse them into a solvent. C_6H_{14} is nonpolar. Interactions between ions and nonpolar molecules tend to be very weak. Thus, the energy required to separate the ions in NaCl is not recovered in the form of ion–C_6H_{14} interactions.
page 535 (a) Separating solvent molecules from each other requires energy and is therefore endothermic. (b) Forming the solute–solvent interactions is exothermic. ***page 537*** The added solute provides a template for the solid to begin to crystallize from solution, and a precipitate will form. ***page 540*** The solubility in water would be considerably lower because there would no longer be hydrogen bonding with water, which promotes solubility. ***page 543*** Dissolved gases become less soluble as temperature increases, and they come out of solution, forming bubbles below the boiling point of water. ***page 545*** 230 ppm (1 ppm is 1 part in10^6); 2.30×10^5 ppb (1 ppb is 1 part in 10^9). ***page 546*** For dilute aqueous solutions the molality will be nearly equal to the molarity. Molality is the number of moles of solute per kilogram of solvent, whereas molarity is the number moles of solute per liter of solution. Because the solution is dilute, the mass of solvent is essentially equal to the mass of the solution. Furthermore, a dilute aqueous solution will have a density of 1.0 kg/L. Thus, the number of liters of solution and the number of kilograms of solvent will be essentially equal. ***page 549*** The lowering of the vapor pressure depends on the total solute concentration (Equation 13.11). One mole of NaCl (a strong electrolyte) provides 2 mol of particles (1 mol of Na^+ and 1 mol Cl), whereas one mole of (a nonelectrolyte) provides only 1 mol particles. ***page 552*** Not necessarily; if the solute is a strong or weak electrolyte, it could have a lower molality and still cause an increase of 0.51 °C. The total molality of all the particles in the solution is 1 m. ***page 555*** The 0.20-m solution is hypotonic with respect to the 0.5-m solution. (A hypotonic solution will have a lower concentration and hence a lower osmotic pressure.) ***page 557*** They would have the same osmotic pressure because they have the same concentration of particles. (Both are strong electrolytes that are 0.20 M in total ions.) ***page 560*** No, hydrophobic groups would face outward to make contact with hydrophobic lipids. ***page 561*** The smaller droplets carry negative charges because of the embedded stearate ions and thus repel one another.

Chapter 14

page 577 Increasing the partial pressure increases the number of collisions between molecules. For any reaction that depends on collisions (which is nearly all of them), we would expect the rate to increase with increasing partial pressure. ***page 580*** You can see visually that the slope of the line connecting 0 s and 600 s is smaller than the slope at 0 s and larger than the slope at 600 s. The order from fastest to slowest is therefore (ii) $>$ (i) $>$ (iii). ***page 583*** Reaction rate is the change in the concentration of a reactant (disappearance) or product (appearance) over a time interval. The rate law governs how the reaction rate depends on the concentrations of the reactants. The rate constant is part of the rate law. ***page 583*** Generally no. Rate always has units of M/s. The units of the rate constant depend on the specific rate law, as we shall see throughout this chapter. ***page 584*** (a) Second order in [NO] and first order in$[H_2]$; (b) The rate increases more when we double [NO]. Doubling [NO] will increase the rate fourfold whereas doubling $[H_2]$ will double the rate. ***page 585*** No. The two reactions could have different rate laws. Only if they have the same rate law and the same value of k will they have the same rate. ***page 592*** After 3 half-lives, the concentration will be 1/8 of its original value, so 1.25 g of the substance remains. ***page 593*** As seen in Equation 14.15, the half-life of a first-order reaction is independent of initial concentration. By contrast, the half-life of a second-order reaction depends on initial concentration (Equation 14.17).
page 596 According to the figure, the energy barrier is lower in the forward direction than in the reverse. Thus, more molecules will have energy sufficient to cross the barrier in the forward direction. The forward rate will be greater ***page 596*** No. If B can be isolated, it can't correspond to the top of the energy barrier. There would be transition states for each of the individual reactions above
page 600 Bimolecular. ***page 603*** To determine the rate, we need to know the elementary reactions that add up to give the balanced equation ***page 605*** The likelihood of three molecules colliding at exactly the same time is vanishingly small. ***page 609*** A heterogeneous catalyst is in a different phase than the reactants and is therefore fairly easy to remove from the mixture. The removal of a homogeneous catalyst can be much more difficult as it exists in the same phase as the reactants. ***page 611*** Yes. Like other catalysts, enzymes speed up reactions by lowering the activation energy, which is the energy of the transition state.

Chapter 15

page 632 (a) The rates of the forward and reverse reactions. (b) Greater than 1 ***page 632*** When the concentrations of reactants and products are no longer changing ***page 635*** It does not depend on starting concentrations. ***page 635*** Units of moles/L are used to calculate K_c; units of partial pressure are used to calculate K_p. ***page 636*** Yes, $K_c = K_p$ when the number of moles of gaseous products and the number of moles of gaseous reactants are equal. ***page 637*** 0.00140 ***page 639*** $K_c = 91$ ***page 639*** It is cubed. ***page 642*** $K_p = P_{H_2O}$ ***page 644*** $K_c = [NH_4^+][OH^-]/[NH_3]$ ***page 652*** (a) to the right, (b) to the left ***page 654*** (bottom) It will shift to the left, the side with a larger number of moles of gas. ***page 655*** As the temperature increases, a larger fraction of molecules in the liquid phase have enough energy to overcome their inter molecular attractions and go into the vapor; the evaporation process is endothermic. Raising the temperature of an endothermic reaction shifts the equilibrium to the right, increasing the amount of gas present. ***page 658*** No, the presence of a catalyst can accelerate the reaction but does not alter the value of K, which is what limits the amount of product produced.

Chapter 16

page 672 The H^+ ion for acids and the OH^- ion for bases.
page 674 CH_3NH_2 is the base because it accepts a H^+ from H_2S as the reaction moves from the left-hand to the right-hand side of the equation. ***page 677*** As the conjugate base of a strong acid, we would classify ClO_4^- as having negligible basicity. ***page 681*** pH is defined as $-\log[H^+]$. This quantity will become negative if the H^+ concentration exceeds 1 M, which is possible. Such a solution would be highly acidic. ***page 683*** pH $= 14.00 - 3.00 = 11.00$. This solution is basic because pH > 7.0. ***page 685*** Both NaOH and $Ba(OH)_2$ are soluble hydroxides. Therefore, the hydroxide concentrations will be 0.001 M for NaOH and 0.002 M for $Ba(OH)_2$. Because the $Ba(OH)_2$ solution has a higher $[OH^-]$, it is more basic and

has a higher pH. ***page 686*** Because CH_3^- is the conjugate base of a substance that has negligible acidity, CH_3^- must be a strong base. Bases stronger than OH^- abstract H^+ from water molecules: $CH_3^- + H_2O \longrightarrow CH_4 + OH^-$. ***page 687*** Oxygen.

page 691 $pH < 7$. We must consider the $[H^+]$ that is due to the autoionization of water. The additional $[H^+]$ from the very dilute acid solution will make the solution acidic.

page 694 $HPO_4^{2-}(aq) \rightleftharpoons H^+(aq) + PO_4^{3-}(aq)$

page 700 4. ***page 702*** Nitrate is the conjugate base of nitric acid, HNO_3. The conjugate base of a strong acid does not act as a base, so NO_3^- ions will not affect the pH. Carbonate is the conjugate base of hydrogen carbonate, HCO_3^-,which is a weak acid. The conjugate base of a weak acid acts as a weak base, so CO_3^{2-} ions will increase the pH. ***page 708*** $HBrO_3$. For an oxyacid, acidity increases as the electronegativity of the central ion increases, which would make $HBrO_2$ more acidic than HIO_2. Acidity also increases as the number of oxygens bound to the central atom increases, which would make $HBrO_3$ more acidic than $HBrO_2$. Combining these two relationships we can order these acids in terms of increasing acid-dissociation constant, $HIO_2 < HBrO_2 < HBrO_3$. ***page 709*** The carboxyl group, —COOH. ***page 710*** It must have an empty orbital that can interact with the lone pair on a Lewis base.

Chapter 17

page 729 (top) The Cl^- ion is the only spectator ion. The pH is determined by the equilibrium

$$NH_3(aq) + H_2O(l) \rightleftharpoons OH^-(aq) + NH_4^+(aq).$$

page 729 (bottom) HNO_3 and NO_3^-. To form a buffer we need comparable concentrations of a weak acid and its conjugate base. HNO_3 and NO_3^- will not form a buffer because HNO_3 is a strong acid and the NO_3^- ion is merely a spectator ion. ***page 731*** (a) The OH^- of NaOH (a strong base) reacts with the acid member of the buffer (CH_3COOH), abstracting a proton. Thus, $[CH_3COOH]$decreases and $[CH_3COO^-]$ increases. (b) The H^+ of HCl (a strong acid) reacts with the base member of the buffer $[CH_3COO^-]$. Thus, $[CH_3COO^-]$decreases and $[CH_3COOH]$increases. ***page 735*** HClO would be more suitable for a $pH = 7.0$ buffer solution. To make a buffer we would also need a salt containing ClO^-, such as NaClO. ***page 740*** The $pH = 7$. The neutralization of a strong base with a strong acid gives a salt solution at the equivalence point. The salt contains ions that do not change the pH of water. ***page 744*** The conjugate base of the weak acid is the majority species in solution at the equivalence point, and this conjugate base reacts with water in a K_b reaction to produce OH^-. Therefore, the pH at the equivalence point for a weak acid/strong base titration is greater than 7.00. ***page 746*** The nearly vertical portion of the titration curve at the equivalence point is smaller for a weak acid–strong base titration; as a result fewer indicators undergo their color change within this narrow range. ***page 746*** The following titration curve shows the titration of 25 mL of Na_2CO_3 with HCl, both with 0.1 *M* concentrations. The overall reaction between the two is

$$Na_2CO_3(aq) + HCl(aq) \longrightarrow 2\,NaCl(aq) + CO_2(g) + H_2O(l)$$

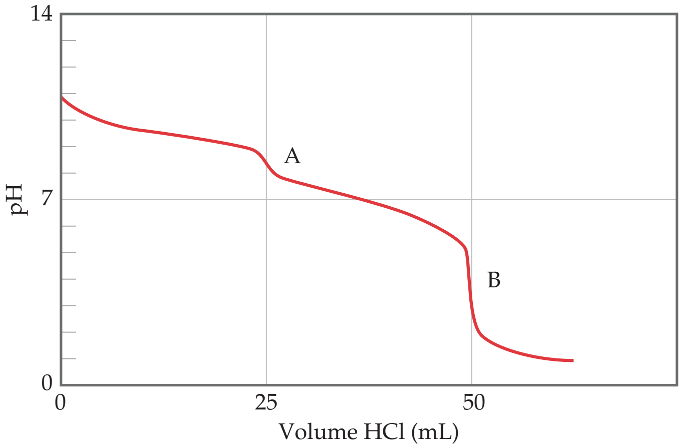
The initial pH (sodium carbonate in water only) is near 11 because CO_3^{2-} is a weak base in water. The graph shows two equivalence points, **A** and **B**. The first point, **A**, is reached at a pH of about 9:

$$Na_2CO_3(aq) + HCl(aq) \longrightarrow NaCl(aq) + NaHCO_3(aq)$$

HCO_3^- is weakly basic in water and is a weaker base than the carbonate ion. The second point, **B**, is reached at a pH of about 4:

$$NaHCO_3(aq) + HCl(aq) \longrightarrow NaCl(aq) + CO_2(g) + H_2O(l)$$

H_2CO_3, a weak acid, forms and decomposes to carbon dioxide and water.



page 749 AgCl. Because all three compounds produce the same number of ions, their relative stabilities correspond directly to the K_{sp} values, with the compound with the largest K_{sp} value being the most soluble. ***page 759*** Amphoteric substances are insoluble in water but dissolve in the presence of sufficient acid or base. Amphiprotic substances can both donate and accept protons. ***page 763*** The solution must contain one or more of the cations in group 1 of the qualitative analysis scheme, Ag^+, Pb^{2+} or Hg_2^{2+}.

Chapter 18

page 777 We would expect that helium is relatively more abundant at the higher elevation, because Earth's gravitational field would exert a greater downward force on the heavier argon atoms. The effect, however, would be small. (new) ***page 780*** In photoionization, a molecule loses an electron upon illumination with radiant energy. In photodissociation, illumination causes rupture of a chemical bond. ***page 781*** Because those molecules do not absorb light at those wavelengths. ***page 783*** Yes; Cl is neither a product nor a reactant in the overall reaction, and its presence does speed the reaction up. ***page 786*** SO_2 in the atmosphere reacts with oxygen to form SO_3. SO_3 in the atmosphere reacts with water in the atmosphere to form H_2SO_4, sulfuric acid. The sulfuric acid dissolves in water droplets that fall to Earth, causing "acid rain" that has a pH of 4 or so. ***page 787*** NO_2 photodissociates to NO and O; the O atoms react with O_2 in the atmosphere to form ozone, which is a key ingredient in photochemical smog.

page 790 Higher humidity means there is more water in the air. Water absorbs infrared light, which we feel as heat. After sundown, the ground that has been warmed earlier in the day reradiates heat out. In locations with higher humidity, this energy is absorbed somewhat by the water and in turn is reradiated to some extent back to the Earth, resulting in warmer temperatures compared to a low-humidity location. ***page 791*** You can see from the phase diagram that to pass from the solid to the gaseous state we need to be below water's critical point. Therefore, to sublime water we need to be below 0.006 atm. A wide range of temperatures will work for sublimation at this pressure—the most environmentally relevant ones are −50 °C to 100 °C. ***page 795*** The pollutants are capable of being oxidized (either directly by reaction with dissolved oxygen or indirectly by the action of organisms such as bacteria). ***page 799*** With a catalyst, the reaction is always faster, therefore costing less energy to run. In addition, with a catalyst the reaction may occur readily at a lower temperature, also costing less energy. ***page 800*** Fossil fuel combustion puts a great deal more CO_2 in the atmosphere right now than any supercritical use of CO_2. Compared to other (halogenated organic) solvents, supercritical CO_2 is far less toxic to life. In addition, the CO_2 used already exists, so we are not making more of it, simply putting some of what exists to an environmentally friendly use. Using CO_2 as a solvent or a reactant in industrial processes is a reasonable choice for environmental sustainability. ***page 801*** Improve efficiency of synthesis of the starting reagent. Improve efficiency of isolating and recycling the acetone and phenol. Improve the activity and cost of production of the catalyst. Work toward using room temperature and room pressure; use water as a solvent if possible; use O_2 as the oxidizing agent instead of hydrogen peroxide if possible. ***page 802*** *sp* before reaction; sp^2 after reaction.

Chapter 19

page 815 No, nonspontaneous processes can occur so long as they receive some continuous outside assistance. Examples of nonspontaneous processes with which we may be familiar include the building of a brick wall and the electrolysis of water to form hydrogen gas and oxygen gas. ***page 817*** No. Just because the system is restored to its original condition doesn't mean that the surroundings have likewise been restored to their original condition, so it is not necessarily reversible. ***page 819*** ΔS depends not merely on q but on q_{rev}. Although there are many possible paths that could take a system from its initial to final state, there is always only one reversible isothermal path between two states. Thus, ΔS has only one particular value regardless of the path taken between states. ***page 821*** Because rusting is a spontaneous process, ΔS_{univ} must be positive. Therefore, the entropy of the surroundings must increase, and that increase must be larger than the entropy decrease of the system. ***page 823*** $S = 0$, based on Equation 19.5 and the fact that $\ln 1 = 0$. ***page 824*** No. Argon atoms are not attached to other atoms, so they cannot undergo vibrational motion. ***page 827*** It must be a perfect crystal at 0 K (third law of thermodynamics), which means it has only a single accessible microstate. ***page 831*** ΔS_{surr} always increases. For simplicity, assume that the process is isothermal. The change in entropy of the surroundings in an isothermal process is $\Delta S_{surr} = \dfrac{-q_{sys}}{T}$. Because the reaction is exothermic, $-q_{sys}$ is a positive number. Thus, ΔS_{surr} is a positive number and the entropy of the surroundings increases. ***page 832*** (a) In any spontaneous process the entropy of the universe increases. (b) In any spontaneous process operating at constant temperature, the free energy of the system decreases. ***page 834*** It indicates that the process to which the thermodynamic quantity refers has taken place under standard conditions, as summarized in Table 19.2. ***page 837*** Above the boiling point, vaporization is spontaneous, and $\Delta G < 0$. Therefore, $\Delta H - T\Delta S < 0$, and $\Delta H < T\Delta S$. Therefore $T\Delta S$ is greater in magnitude. ***page 841*** No. K is the ratio of product concentration to reactant concentration at equilibrium; K could be very small but is not zero.

Chapter 20

page 859 Oxygen is first assigned an oxidation number of -2. Nitrogen must then have a $+3$ oxidation number for the sum of oxidation numbers to equal -1, the charge of the ion. ***page 862*** No. Electrons should appear in the two half-reactions but cancel when the half-reactions are added properly. ***page 869*** Yes. A redox reaction with a positive standard cell potential is spontaneous under standard conditions. ***page 871*** 1 atm pressure of $Cl_2(g)$ and 1 M concentration of $Cl^-(aq)$ ***page 873*** Ni ***page 877*** Sn^{2+} ***page 893*** Al, Zn. Both are easier to oxidize than Fe.

Chapter 21

page 911 The mass number decreases by 4. ***page 913*** Only the neutron, as it is the only neutral particle listed. ***page 918*** From Figure 21.4 we can see that each of these four elements has only one stable isotope, and from their atomic numbers we see that they each have an odd number of protons. Given the rarity of stable isotopes with odd numbers of neutrons and protons, we expect that each isotope will possess an even number of neutrons. From their atomic weights we see that this is the case: F (10 neutrons), Na (12 neutrons), Al (14 neutrons), and P (16 neutrons). ***page 920*** No. Electric and magnetic fields are only effective at accelerating charged particles and a neutron is not charged. ***page 923*** It doubles as well. The number of disintegrations per second is proportional to the number of atoms or the radioactive isotope. ***page 924*** No; changing the mass would not change the half-life as shown in Equation 21.20. ***page 926*** Alpha radiation, which has the smallest relative penetrating power (Table 21.1). ***page 927*** Any process that depends on the mass of the molecule, such as the rate of gaseous effusion (Section 10.8) ***page 931*** (top) The values in Table 21.7 only reflect the mass of the nucleus, while the atomic mass is the sum of the mass of the nucleus and the electrons. So the atomic mass of iron-56 is $26 \times m_e$ larger than the nuclear mass. ***page 931*** (bottom) No. Stable nuclei having mass numbers around 100 are the most stable nuclei. They could not form a still more stable nucleus with an accompanying release of energy. ***page 941*** The absorbed dose is equal to $0.10\ J \times (1\ rad/1 \times 10^{-2}\ J) = 10$ rads. The effective dosage is calculated by multiplying the absorbed dose by the relative biological effectiveness (RBE) factor, which is 10 for alpha radiation. Thus, the effective dosage is 100 rems.

Chapter 22

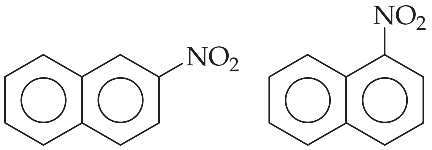
page 955 No. There is a triple bond in N_2. P does form triple bonds, as it would have to in order to form P_2. ***page 957*** H^-, hydride. ***page 958*** $+1$ for everything except H_2, for which the oxidation state of H is 0. ***page 964*** 0 for Cl_2; -1 for Cl^-; $+1$ for ClO^- ***page 966*** They should both be strong, since the central halogen is in the $+5$ oxidation state for both of them. We need to look up the redox potentials to see which ion, BrO_3^- or ClO_3^-, has the larger reduction potential. The ion with the larger reduction potential is the stronger oxidizing agent. BrO_3^- is the stronger oxidizing agent on this basis ($+1.52$ V standard reduction potential in acid compared to $+1.47$ V for ClO_3^-). ***page 968*** HIO_3 ***page 972*** $SO_3(g) + H_2O(l) \longrightarrow H_2SO_4(l)$ ***page 976*** (a) $+5$ (b) $+3$ ***page 978*** In PF_3, phosphorus in the $+3$ oxidation state. The reaction with water produces the oxyacid with phosphorus in that oxidation state, H_3PO_3. Thus, the reaction is analogous to Equation 22.53, which also shows a trihalide reacting with water. ***page 982*** $CO_2(g)$ ***page 987*** Silicon is the element, Si. Silica is SiO_2. Silicones are polymers that have an O—Si—O backbone and hydrocarbon groups on the Si. ***page 988*** $+3$

Chapter 23

page 999 Sc has the largest radius. ***page 1001*** Because titanium only has 4 valence electrons you would have to remove a core electron to create a Ti^{5+} ion. ***page 1002*** The larger the distance, the weaker the spin–spin interactions. ***page 1002*** Yes, it is a Lewis acid–base interaction; the metal ion is the Lewis acid (electron pair acceptor). ***page 1007*** The nonbonding electron pairs in H_2O are both located on the same atom, which makes it impossible for both pairs to be donated to the same metal atom. To act as a chelating agent the nonbonding electron pairs need to be on different atoms that are not connected to each other. ***page 1009*** Bidentate. ***page 1011*** The porphine ligand contains a conjugated system of pi bonds (alternating single and double bonds), which allows it to absorb visible light. ***page 1015*** No, ammonia cannot engage in linkage isomerism—the only atom that can coordinate to a metal is the nitrogen. ***page 1018*** Both isomers have the same chemical formulas and the same donor atoms on the ligands bonding to the metal ion. The difference is that the *d* isomer has a right-handed "twist" and the *l* isomer has a "left-handed" twist. ***page 1021*** (a) Co is $[Ar]\,4s^23d^7$. (b) Co^{3+} is $[Ar]\,3d^6$. The Co atom has 3 unpaired electrons and the Co^{3+} ion has 4 unpaired electrons, assuming all five d orbitals have the same energy. ***page 1023*** Because Ti(IV) ions have an $[Ar]\,3d^0$ electron configuration there are no *d-d* transitions that can absorb photons of visible light. ***page 1025*** d^4, d^5, d^6, d^7. ***page 1027*** Because the ligands are located in the *xy* plane, electrons in a d_{xy} orbital, which has its lobes in the *xy* plane, feel more repulsion than electrons in the d_{xz} and d_{yz} orbitals.

Chapter 24

page 1043 C═N, because it is a polar double bond. C—H and C—C bonds are relatively unreactive. (The CN double bond does not have to fully break to be reactive.) ***page 1045*** Two C—H bonds and two C—C bonds ***page 1046*** The isomers have different properties, as seen in Table 24.3 (e.g., different melting points and different boiling points). ***page 1049*** Yes, since cyclopropane is more strained. ***page 1051*** Only two of the four possible C═C bond sites are distinctly different in the linear chain of five carbon atoms with one double bond. ***page 1058***



page 1063 Reduction, which is the reverse of oxidation. ***page 1063*** $CH_3CH_2CH_2CH_2COOH$ ***page 1064*** The generic formula of an ether is ROR′, while an ester is RCOOR′. If you carbonylate or oxidize an ether, you can get an ester. ***page 1067*** All four groups must be different from one another. ***page 1071*** No. Breaking the hydrogen bonds between N—H and O═C groups in a protein by heating causes the α-helix structure to unwind and the β-sheet structure to separate. ***page 1076*** The alpha form of the C—O—C linkage. Glycogen serves as a source of energy in the body, which means that the body's enzymes must be able to hydrolyze it to sugars. The enzymes work only on polysaccharides having the α linkage.

ANSWERS TO GO FIGURE

Chapter 1

Figure 1.1 Aspirin. It contains 9 carbon atoms. ***Figure 1.4*** Vapor (gas) ***Figure 1.5*** Molecules of a compound are composed of more than one type of atom, and molecules of an element are composed of only one type of atom. ***Figure 1.6*** Earth is rich in silicon and aluminum; the human body is rich in carbon and hydrogen ***Figure 1.7*** The relative volumes are in direct proportion t to the number of molecules ***Figure 1.14*** The separations are due to physical processes of adsorption of the materials onto the column ***Figure 1.17*** True ***Figure 1.18*** 1000 ***Figure 1.22*** The darts would be scattered widely (poor precision) but their average position would be at the center (good accuracy).

Chapter 2

Figure 2.3 We know the rays travel from the cathode because the rays are deflected by the magnetic field as though coming from the left. ***Figure 2.4*** The electron beam would be deflected downward because of repulsion by the upper negative plate and attraction toward the positive plate. ***Figure 2.5*** No, the electrons are of negligible mass compared with an oil drop. ***Figure 2.7*** The beta rays, whose path is diverted away from the negative plate and toward the positive plate, consist of electrons. Because the electrons are much less massive than the alpha particles, their motion is affected more strongly by the electric field. ***Figure 2.9*** The beam consists of alpha particles, which carry a +2 charge. ***Figure 2.10*** 10^{-2} pm ***Figure 2.13*** Based on the periodic trend, we expect that elements that precede a nonreactive gas, as F does, will also be reactive nonmetals. The elements fitting this pattern are H and Cl. ***Figure 2.15*** The metals are in the form of solid blocks, or relatively large pieces, as opposed to powders. They have a metallic sheen that is missing from the nonmetals. The nonmetals more readily form powders, and are more varied in color and consistency than metals. ***Figure 2.17*** The ball-and-stick model. ***Figure 2.18*** The elements are in the following groups: Ag^+ is 1B, Zn^{2+} is 2B, and Sc^{3+} is 3B. Sc^{3+} has the same number of electrons as Ar (element 18). ***Figure 2.21*** It is a difference in a physical property, color. ***Figure 2.22*** Removing one O atom from the perbromate ion gives the bromate ion, BrO_3^-.

Chapter 3

Figure 3.4 There are two CH_4 and four O_2 molecules on the reactant side, which contain 2 C atoms, 8 H atoms and 8 O atoms. The number of each type of atom remains the same on the product side as it must. ***Figure 3.8*** The flame gives off heat and therefore the reaction must release heat. ***Figure 3.9*** As shown, 18.0 g $H_2O = 1$ mol $H_2O = 6.02 \times 10^{23}$ molecules H_2O. Thus, 9.00 g $H_2O = 0.500$ mol $H_2O = 3.01 \times 10^{23}$ molecules H_2O. ***Figure 3.12*** (a) The molar mass of CH_4, 16.0 g CH_4/1 mol CH_4. (b) Avogadro's number, 1 mol $CH_4/6.02 \times 10^{23}$ formula units CH_4, where a formula unit in this case is a molecule. ***Figure 3.17*** If the amount of H_2 is doubled then O_2 becomes the limiting reactant. In that case $(7 \text{ mol } O_2) \times (2 \text{ mol } H_2O/1 \text{ mol } O_2) = 14$ mol H_2O would be produced.

Chapter 4

Figure 4.3 NaCl(*aq*) ***Figure 4.4*** K^+ and NO_3^- ***Figure 4.9*** Two moles of hydrochloric acid are needed to react with each mole of $Mg(OH)_2$. ***Figure 4.12*** Two. Each O atom becomes an O^{2-} ion. ***Figure 4.13*** One, based on the reaction stoichiometry. ***Figure 4.14*** Because the Cu(II) ion produces a blue color in aqueous solution. ***Figure 4.18*** The volume needed to reach the end point if $Ba(OH)_2(aq)$ were used would be one-half the volume needed for titration with NaOH(*aq*), because there are two hydroxide ions for every barium ion.

Chapter 5

Figure 5.1 In the act of throwing, the pitcher transfers energy to the ball, which then becomes kinetic energy of the ball. For a given amount of energy E transferred to the ball, Equation 5.1 tells us that the speed of the ball is $v = \sqrt{2E/m}$ where m is the mass of the ball. Because a baseball has less mass than a bowling bowl, it will have a higher speed for a given amount of energy transferred. ***Figure 5.2*** When she starts going uphill, kinetic energy is converted to potential energy and her speed decreases. ***Figure 5.3*** The electrostatic potential energy of two oppositely charged particles is negative (Equation 5.2). As the particles become closer, the electrostatic potential energy becomes even more negative—that is, it decreases. ***Figure 5.4*** Yes, the system is still closed—matter can't escape the system to the surroundings unless the piston is pulled completely out of the cylinder. ***Figure 5.5*** If $E_{\text{final}} = E_{\text{initial}}$, then $\Delta E = 0$. ***Figure 5.6***

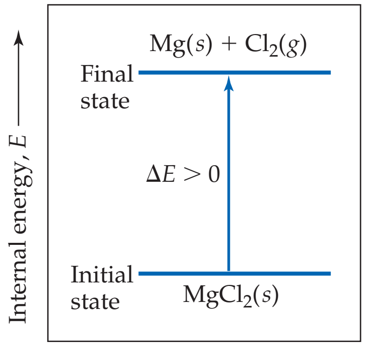


Figure 5.7 $\Delta E = 50\text{ J} + (-85\text{ J}) = -35\text{ J}$ ***Figure 5.10*** The battery is doing work on the surroundings, so $w < 0$. ***Figure 5.11*** We need to know whether Zn(*s*) or HCl(*aq*) is the limiting reagent of the reaction. If it is Zn(*s*), then the addition of more Zn will lead to the generation of more $H_2(g)$ and more work will be done. ***Figure 5.16*** Endothermic—heat is being added to the system to raise the temperature of the water. ***Figure 5.17*** Two cups provide more thermal insulation so less heat will escape the system. ***Figure 5.18*** The stirrer ensures that all of the water in the bomb is at the same temperature. ***Figure 5.20*** The condensation of 2 $H_2O(g)$ to 2 $H_2O(l)$ ***Figure 5.21*** Yes, ΔH_3 would remain the same as it is the enthalpy change for the process $CO(g) + \frac{1}{2}O_2(g) \longrightarrow CO_2(g)$. ***Figure 5.23*** Grams of fat

Chapter 6

Figure 6.3 Wavelength = 1.0 m, frequency = 3.0×10^8 cycles/s. ***Figure 6.4*** Longer by 3 to 5 orders of magnitude (depending on what part of the microwave spectrum is considered). ***Figure 6.5*** The hottest area is the white or yellowish white area in the center. ***Figure 6.7*** The energy comes from the light shining on the surface. ***Figure 6.12*** The $n = 2$ to $n = 1$ transition involves a larger energy change than the $n = 3$ to $n = 2$ transition. (Compare the space differences between the states in the figure.) If the $n = 3$ to $n = 2$ transition produces visible light, the $n = 2$ to $n = 1$ transition must produce radiation of greater energy. The infrared radiation has lower frequency and, hence, lower energy than visible light, whereas ultraviolet radiation has higher frequency and greater energy. Thus, the $n = 2$ to $n = 1$ transition is more likely to produce ultraviolet radiation. ***Figure 6.13*** The $n = 4$ to $n = 3$ transition involves a smaller energy difference and will therefore emit light of longer wavelength. ***Figure 6.17*** The region of highest electron density is where the density of dots is highest, which is near the nucleus.

Figure 6.18 The fourth shell $(n = 4)$ would contain four subshells, labeled 4*s*, 4*p*, 4*d*, and 4*f*. ***Figure 6.19*** There would be four maxima and three nodes. ***Figure 6.23*** (a) The intensity of the color indicates that the probability of finding the electron is greater at the interior of the lobes than on the edges. (b) $2p_x$. ***Figure 6.24*** The d_{z^2} orbital has two large lobes that look like those of a *p* orbital, but also has a "doughnut" around the middle. ***Figure 6.25*** The 4*d* and 4*f* subshells are not shown. ***Figure 6.26*** In this pictorial view of spin, there are only two directions in which the electron can spin ***Figure 6.31*** Osmium

Chapter 7

Figure 7.1 These three metals do not readily react with other elements, especially oxygen, so they are often found in nature in the elemental form as metals (such as gold nuggets) ***Figure 7.4*** Yes, because of the peak near the nucleus in the 2*s* curve there is a probability, albeit small, that a 2*s* electron will be closer to the nucleus than a 1*s* electron. ***Figure 7.7*** Bottom and left ***Figure 7.8*** They get larger, just like the atoms do. ***Figure 7.10*** 900 kJ/mol ***Figure 7.11*** There is more electron–electron repulsion in the case of oxygen because two electrons have to occupy the same orbital. ***Figure 7.12*** The added electron for the Group 4A elements leads to a half-filled np^3 configuration. For the Group 5A elements, the added electron leads to an np^4 configuration, so the electron must be added to an orbital that already has one electron in it. ***Figure 7.13*** They are opposite: As ionization energy increases, metallic character decreases, and vice versa.

Figure 7.15 Anions are above and to the right of the line; cations are below and to the left of the line. ***Figure 7.16*** No. The Na^+ and NO_3^- ions will simply be spectator ions. The H^+ ions of an acid are needed in order to dissolve NiO. ***Figure 7.17*** No. As seen in the photo, sulfur crumbles as it is hit with a hammer, typical of a solid nonmetal. ***Figure 7.21*** Because Rb is below K in the periodic table, we expect Rb to be more reactive with water than K. ***Figure 7.23*** Lilac (see Figure 7.22). ***Figure 7.25*** The bubbles are due to $H_2(g)$. This could be confirmed by carefully testing the bubbles with a flame—there should be popping as the hydrogen gas ignites.

Figure 7.26 Water does not decompose on sitting the way that hydrogen peroxide does. ***Figure 7.27*** A regular octagon.

Figure 7.28 I_2 is a solid whereas Cl_2 is a gas. Molecules are more closely packed together in a solid than they are in a gas, as will be discussed in detail in Chapter 11.

Chapter 8

Figure 8.1 We would draw the chemical structure of sugar molecules (which have no charges and have covalent bonding between atoms in each molecule) and indicate weak intermolecular forces (especially hydrogen bonding) between sugar molecules. ***Figure 8.2*** Yes, the same sort of reaction should occur between any of the alkali metals and any of the elemental halogens. ***Figure 8.3*** Cations have a smaller radius than their neutral atoms and anions have a larger radius. Because Na and Cl are in the same row of the periodic table, we would expect Na^+ to have a smaller radius than Cl^-, so we would infer that the larger green spheres represent the chloride ions and the smaller purple spheres represent the sodium ions. ***Figure 8.4*** The distance between ions in KF should be larger than that in NaF and smaller than that in KCl. We would thus expect the lattice energy of KF to be between 701 and 910 kJ/mol. ***Figure 8.6*** The repulsions between the nuclei would decrease, the attractions between the nuclei and the electrons would decrease, and the repulsions between the electrons would be unaffected. ***Figure 8.7*** The electronegativity decreases with increasing atomic number. ***Figure 8.9*** μ will decrease

Figure 8.10 The bonds are not polar enough to cause enough excess electron density on the halogen atom to lead to a red shading.

Figure 8.12 The lengths of the bonds of the outer O atoms to the inner O atom are the same. ***Figure 8.13*** Yes. The electron densities on the left and right parts of the molecule are the same, indicating that resonance has made the two O — O bonds equivalent to one another. ***Figure 8.14*** The dashed bonds represent the "half bonds" that result when the two resonance structures are averaged.

Figure 8.15 Exothermic ***Figure 8.17*** It should be halfway between the values for single and double bonds, which we can estimate to be about 280 kJ/mol from the graph.

Chapter 9

Figure 9.1 The radii of the atoms involved (see Section 7.3).

Figure 9.3 Octahedral. ***Figure 9.4*** No. We will get the same bent-shaped geometry regardless of which two atoms we remove.

Figure 9.7 The electron pair in the bonding domain is attracted to two nuclei, whereas the nonbonding pair is attracted to only one nucleus. ***Figure 9.8*** 90°. ***Figure 9.9*** The C — O — H bond involving the right O because of the greater repulsions due to the nonbonding electron domains. The angle should be less than the ideal value of 109.5°. ***Figure 9.10*** Zero. Because they are equal in magnitude but opposite in sign, the vectors cancel upon addition. ***Figure 9.13*** The Cl 3*p* orbital extends farther in space than does the H 1*s* orbital. Thus, the Cl 3*p* orbital can achieve an effective overlap with a H 1*s* orbital at a longer distance. ***Figure 9.14*** At very short internuclear distances the repulsion between the nuclei causes the potential energy to rise rapidly. ***Figure 9.16*** The hybrid orbitals have to overlap with the 2*p* orbitals of the F atoms. The large lobes of the hybrid orbitals will lead to a much more effective overlap. ***Figure 9.17*** 120°.

Figure 9.18 The p_z orbital. ***Figure 9.19*** No. All four hybrids are equivalent and the angles between them are all the same, so we can use any of the two to hold the nonbonding pairs. ***Figure 9.20*** Because the P 3*p* orbitals are larger than the N 2*p* orbitals, we would expect somewhat larger lobes on the hybrid orbitals in the right-most drawing. Other than that, the molecules are entirely analogous.

Figure 9.23 They have to lie in the same plane in order to allow the overlap of the π orbitals to be effective in forming the π bond.

Figure 9.24 Acetylene should have the higher carbon-carbon bond energy because it has a triple bond as compared to the double bond in ethylene. ***Figure 9.26*** It has six C — C σ and six C — H σ bonds. ***Figure 9.32*** Zero. A node, by definition, is the place where the value of the wave function is zero.

Figure 9.33 The energy of σ_{1s} would rise (but would still be below the energy of the H 1*s* atomic orbitals). ***Figure 9.34*** The two electrons in the σ_{1s} MO. ***Figure 9.35*** σ^*_{1s} and σ^*_{2s}. ***Figure 9.36*** The end-on overlap in the σ_{2p} MO is greater than the sideways overlap in the π_{2p}.

Figure 9.42 The σ_{2p} and π_{2p} MOs have switched order.

Figure 9.43 F_2 contains four more electrons than N_2. These electrons go into the antibonding π^*_{2p} orbitals, thus lowering the bond order. ***Figure 9.45*** N_2 is diamagnetic so it would not be attracted to the magnetic field. The liquid nitrogen would simply pour through the poles of the magnet without "sticking." ***Figure 9.46*** 11. All the electrons in the $n = 2$ level are valenceshell electrons.

Chapter 10

Figure 10.2 It will increase. ***Figure 10.4*** Decreases

Figure 10.5 1520 torr or 2 atm ***Figure 10.6*** Linear

Figure 10.9 one ***Figure 10.10*** Chlorine, Cl_2. ***Figure 10.13*** About one-sixth ***Figure 10.14*** O_2 has the largest molar mass, 32 g/mol, and H_2 has the smallest, 2.0 g/mol. ***Figure 10.16*** *n*, moles of gas

Figure 10.20 True ***Figure 10.22*** It would increase.

Chapter 11

Figure 11.2 The density in a liquid is much closer to a solid than it is to a gas. ***Figure 11.3*** The distance within the molecule (the covalent bond distance) represented by the solid black line is smaller than the intermolecular distance represented by the red dotted line. ***Figure 11.5*** The halogens are diatomic molecules and have much greater size and mass, and therefore greater polarizability, than the noble gases, which are monatomic.

Figure 11.8 They stay roughly the same because the molecules have roughly the same molecular weights. Thus, the change in boiling point moving left to right is due mainly to the increasing dipole-dipole attractions.

Figure 11.9 Both compounds are nonpolar and incapable of forming hydrogen bonds. Therefore, the boiling point is determined by the dispersion forces, which are stronger for the larger, heavier SnH_4. ***Figure 11.10*** The non-hydrogen atom must possess a nonbonding electron pair. ***Figure 11.11*** There are four electron pairs surrounding oxygen in a water molecule. Two of the electron pairs are used to make covalent bonds to hydrogen within the H_2O molecule, while the other two are available to make hydrogen bonds to neighboring molecules. Because the electron-pair geometry is tetrahedral (four electron domains around the central atom), the $H — O \cdots H$ bond angle is approximately 109°. ***Figure 11.13*** The O atom is the negative end of the polar H_2O molecule; the negative end of the dipole is attracted to the positive ion. ***Figure 11.14*** There are no ions present, but when we ask, "Are polar molecules present?" we make a distinction between the two molecules because SiH_4 is nonpolar and SiH_2Br_2 is polar. ***Figure 11.19*** Wax is a hydrocarbon that cannot form hydrogen bonds. Therefore, coating the inside of tube with wax will dramatically decrease the adhesive forces between water and the tube and change the shape of the water meniscus to an inverted U-shape. Neither wax nor glass can form metallic bonds with mercury so the shape of the mercury meniscus will be qualitatively the same, an inverted U-shape. ***Figure 11.20*** Because energy is a state function, the energy to convert a gas to a solid is the same regardless of whether the process occurs in one or two steps. Thus, the energy of deposition equals the energy of condensation plus the energy of freezing. ***Figure 11.21*** Because we are dealing with a state function, the energy of going straight from a solid to a gas must be the same as going from a solid to a gas through an intermediate liquid state. Therefore, the heat of sublimation must be equal to the sum of the heat of fusion and the heat of vaporization: $\Delta H_{\text{sub}} = \Delta H_{\text{fus}} + \Delta H_{\text{vap}}$. ***Figure 11.22*** The temperature of the liquid water is increasing. ***Figure 11.24*** Increases, because the molecules have more kinetic energy as the temperature increases and can escape more easily ***Figure 11.25*** All liquids including ethylene glycol reach their normal boiling point when their vapor pressure is equal to atmospheric pressure, 760 torr. ***Figure 11.27*** It must be lower than the temperature at the triple point.

Chapter 12

Figure 12.5 There is not a centered square lattice, because if you tile squares and put lattice points on the corners and the center of each square it would be possible to draw a smaller square (rotated by 45°) that only has lattice points on the corners. Hence a "centered square lattice" would be indistinguishable from a primitive square lattice with a smaller unit cell. ***Figure 12.12*** Face-centered cubic, assuming similar size spheres and cell edge lengths, since there are more atoms per volume for this unit cell compared to the other two. ***Figure 12.13*** A hexagonal lattice ***Figure 12.15*** The solvent is the majority component and the solute the minority component. Therefore, there will be more solvent atoms than solute atoms. ***Figure 12.17*** The samarium atoms sit on the corners of the unit cell so there is only $8 \times (1/8) = 1$ Sm atom per unit cell. Eight of the nine cobalt atoms sit on faces of the unit cell, and the other sits in the middle of the unit cell so there are $8 \times (1/2) + 1 = 5$ Co atoms per unit cell. ***Figure 12.19*** P_4, S_8, and Cl_2 are all molecules, because they have strong chemical bonds between atoms and have well-defined numbers of atoms per molecule. ***Figure 12.21*** In the fourth period, vanadium and chromium have very similar melting points. Molybdenum and tungsten have the highest melting points in the fifth and sixth periods, respectively. All of these elements are located near the middle of the period where the bonding orbitals are mostly filled and the antibonding orbitals mostly empty. ***Figure 12.22*** The molecular orbitals become more closely spaced in energy. ***Figure 12.23*** Potassium has only one valence electron per atom ($4s^1$). Therefore we expect the $4s$ band to be approximately half full. If we fill the $4s$ band halfway a small amount of electron density might leak over and start to fill the $3d$ orbitals as well. The $4p$ orbitals should be empty. ***Figure 12.24*** Ionic substances cleave because the nearest neighbor interactions switch from attractive to repulsive if the atoms slide so that ions of like charge (cation–cation and anion–anion) touch each other. Metals don't cleave because the atoms are attracted to all other atoms in the crystal through metallic bonding. ***Figure 12.25*** No, ions of like charge do not touch in an ionic compound because they are repelled from one another. In an ionic compound the cations touch the anions. ***Figure 12.27*** In NaF there are four Na^+ ions $(12 \times 1/4)$ and four F^- ions $(8 \times 1/8 + 6 \times 1/2)$ per unit cell. In MgF_2 there are two Mg^{2+} ions $(8 \times 1/8 + 1)$ and four F^- ions $(4 \times 1/2 + 2)$ per unit cell. In ScF_3 there is one Sc^{3+} ion $(8 \times 1/8)$ and three F^- ions $(12 \times 1/4)$ per unit cell. ***Figure 12.28*** The intermolecular forces are stronger in toluene, as shown by its higher boiling point. The molecules pack more efficiently in benzene, which explains its higher melting point, even though the intermolecular forces are weaker. ***Figure 12.30*** The band gap for an insulator would be larger than the one for a semiconductor. ***Figure 12.31*** If you doubled the amount of doping in panel (b), the amount of blue shading the conduction band would also double. ***Figure 12.44*** Decrease. As the quantum dots get smaller, the band gap increases and the emitted light shifts to shorter wavelength. ***Figure 12.47*** Each carbon atom in C_{60} is bonded to three neighboring carbon atoms through covalent bonds. Thus, the bonding is more like graphite, where carbon atoms also bond to three neighbors, than diamond, where carbon atoms bond to four neighbors.

Chapter 13

Figure 13.1 Gas molecules move in constant random motion. ***Figure 13.2*** Opposite charges attract. The electron-rich O atom of the H_2O molecule, which is the negative end of the dipole, is attracted to the positive Na^+ ion. ***Figure 13.3*** The negative end of the water dipole (the O) is attracted to the positive Na^+ ion, whereas the positive end of the dipole (the H) is attracted to the negative Cl^- ion. ***Figure 13.4*** For exothermic solution processes the magnitude of ΔH_{mix} will be larger than the magnitude of $\Delta H_{solute} + \Delta H_{solvent}$ ***Figure 13.6*** 237.6 g/mol, which includes the waters of hydration. ***Figure 13.7*** If the solution wasn't supersaturated, solute would not crystallize from it. ***Figure 13.12*** If the partial pressure of a gas over a solution is doubled, the concentration of gas in the solution would double. ***Figure 13.13*** The slopes increase as the molecular weight increases. The larger the molecular weight, the greater the polarizability of the gas molecules, leading to greater intermolecular attractive forces between gas molecules and water molecules. ***Figure 13.15*** Looking at where the solubility curves for KCl and NaCl intersect the 80 °C line, we see that the solubility of KCl is about 51 g/100 g H_2O, whereas NaCl has a solubility of about 39 g/100 g H_2O. Thus, KCl is more soluble than NaCl at this temperature. ***Figure 13.16*** N_2 has the same molecular weight as CO but is nonpolar, so we can predict that its curve will be just below that of CO. ***Figure 13.22*** The water will move through the semipermeable membrane toward the more concentrated solution. Thus, the liquid level in the left arm will increase. ***Figure 13.23*** Water will move toward the more concentrated solute solution, which is inside the red blood cells, causing them to undergo hemolysis. ***Figure 13.26*** The negatively charged groups both have the composition $—CO_2^-$. ***Figure 13.28*** Recall the rule that likes dissolve likes. The oil drop is composed of nonpolar molecules, which interact with the nonpolar part of the stearate ion via dispersion forces.

Chapter 14

Figure 14.2 No. The surface area of a steel nail is much smaller than that for the same mass of steel wool, so the reaction with O_2 would not be as vigorous. Depending on how hot it is, it might not burn at all. ***Figure 14.3*** Our first guess might be half way between the values at 20 s and 40 s, namely 0.41 mol A. However, we also see that the change in the number of moles of A between 0 s and 20 s is greater than that between 20 s and 40 s—in other words, the rate of conversion gets smaller as the amount of A decreases. So we would guess that the change from 20 s to 30 s is greater than the change from 30 s to 40 s, and we would estimate that the number of moles of A is between 0.41 and 0.30 mol. ***Figure 14.4*** The instantaneous rate

decreases as the reaction proceeds. ***Figure 14.8*** The reaction is first order. ***Figure 14.10*** At the beginning of the reaction when both plots are linear or nearly so. ***Figure 14.13*** The reaction that causes the light occurs more slowly at lower temperatures than at higher ones. ***Figure 14.14*** No, it will not turn down. The rate constant increases monotonically with increasing temperature because the kinetic energy of the colliding molecules continues to increase. ***Figure 14.16*** He would not need to hit the ball as hard; that is, less kinetic energy would be required if the barrier were lower. ***Figure 14.17*** As shown, the magnitude of energy needed to overcome the energy barrier is greater than the magnitude of the energy change in the reaction. ***Figure 14.18*** It would be more spread out, the maximum of the curve would be lower and to the right of the maximum of the red curve, and a greater fraction of molecules would have kinetic energy greater than E_a than for the red curve. ***Figure 14.20*** As shown, it is easier to convert to products because the activation energy is lower in that direction. ***Figure 14.21*** It can't be determined. If the amount of backup at the two toll plazas is roughly the same in the two scenarios, the time to get from point 1 to point 3 will be about the same. ***Figure 14.22*** The color is characteristic of molecular bromine, Br_2, which is present in appreciable quantities only in the middle photo. ***Figure 14.23*** The intermediate is at the valley in the middle of the blue curve. The transition states are the peaks, one for the red curve and two for the blue curve. ***Figure 14.26*** Grinding increases the surface area, exposing more of the catalase to react with the hydrogen peroxide. ***Figure 14.27*** Substrates must be held more tightly so that they can undergo the desired reaction. Products are released from the active site.

Chapter 15

Figure 15.1 The same because once the system reaches equilibrium the concentrations of NO_2 and N_2O_4 stop changing. ***Figure 15.2*** Greater than 1 ***Figure 15.6*** The boxes would be approximately the same size. ***Figure 15.7*** It would decrease. To reestablish equilibrium the concentration of $CO_2(g)$ would need to return to its previous value. The only way to do that would be for more $CaCO_3$ to decompose to produce enough $CO_2(g)$ to replace what was lost. ***Figure 15.9*** High pressure and low temperature, 500 atm and 400 °C in this figure. ***Figure 15.10*** Nitrogen must react with some of the added hydrogen to create ammonia and restore equilibrium. ***Figure 15.14*** (a) the energy difference between the initial state and the transition state. ***Figure 15.15*** About 5×10^{-4}

Chapter 16

Figure 16.2 Hydrogen bonds. ***Figure 16.4*** $O^{2-}(aq) + H_2O(l) \longrightarrow 2\,OH^-(aq)$. ***Figure 16.5*** Basic. The mixture of the two solutions will still have $[H^+] < [OH^-]$. ***Figure 16.6*** Lemon juice. It has a pH of about 2 whereas black coffee has a pH of about 5. The lower the pH, the more acidic the solution. ***Figure 16.8*** Phenolphthalein changes from colorless, for pH values less than 8, to pink for pH values greater than 10. A pink color indicates pH > 10. ***Figure 16.9*** Bromothymol blue would be most suitable because it changes pH over a range that brackets pH = 7. Methyl red is not sensitive to pH changes when pH > 6, while phenolphthalein is not sensitive to pH changes when pH < 8, so neither changes color at pH = 7. ***Figure 16.12*** Yes. The equilibrium of interest is $H_3CCOOH \rightleftharpoons H^+ + H_3CCOO^-$. If the percent dissociation remained constant as the acid concentration increased, the concentration of all three species would increase at the same rate. However, because there are two products and only one reactant, the product of the concentrations of products would increase faster than the concentration of the reactant. Because the equilibrium constant is constant, the percent dissociation decreases as the acid concentration increases. ***Figure 16.13*** The acidic hydrogens belong to carboxylate (—COOH) groups, whereas the fourth proton bound to oxygen is part of a hydroxyl (—OH) group. In organic acids, like citric acid, the acidic protons are almost always part of a carboxylate group. ***Figure 16.14*** The nitrogen atom in hydroxylamine accepts a proton to form NH_3OH^+. As a general rule, nonbonding electron pairs on nitrogen atoms are more basic than nonbonding electron pairs on oxygen atoms. ***Figure 16.16*** The range of pH values is so large that we can't show the effects using a single indicator (see Figure 16.8). ***Figure 16.18*** Yes. HI is a strong acid, which is consistent with the trends shown in the figure. ***Figure 16.19*** The HOY molecule on the left because it is a weak acid. Most of the HOY molecules remain undissociated.

Chapter 17

Figure 17.6 The pH will increase upon addition of the base. ***Figure 17.7*** 25.00 mL. The number of moles of added base needed to reach the equivalence point remains the same. Therefore, by doubling the concentration of added base the volume needed to reach the equivalence point is halved. ***Figure 17.9*** The volume of base needed to reach the equivalence point would not change because this quantity does not depend on the strength of the acid. However, the pH at the equivalence point, which is greater than 7 for a weak acid–strong base titration, would decrease to 7 because hydrochloric acid is a strong acid. ***Figure 17.11*** The pH at the equivalence point increases (becomes more basic) as the acid becomes weaker. The volume of added base needed to reach the equivalence point remains unchanged. ***Figure 17.12*** Yes. Any indicator that changes color between pH = 3 and pH = 11 could be used for a strong acid–strong base titration. Methyl red changes color between pH values of approximately 4 and 6. ***Figure 17.22*** ZnS and CuS would both precipitate on addition of H_2S, preventing separation of the two ions. ***Figure 17.23*** Yes. CuS would precipitate in step 2 on addition of H_2S to an acidic solution, while the Zn^{2+} ions remained in solution.

Chapter 18

Figure 18.1 About 85 km, at the mesopause. ***Figure 18.3*** The atmosphere absorbs a significant fraction of solar radiation. ***Figure 18.4*** The peak value is about 5×10^{12} molecules per cm^3. If we use Avogradro's number to convert molecules to moles, and the conversion factor of $1000\ cm^3 = 1000\ mL = 1\ L$, we find that the concentration of ozone at the peak is 8×10^{-9} mole/L. ***Figure 18.7*** The major sources of sulfur dioxide emission are located in the eastern half of the United States, and prevailing winds carry emissions in an eastward direction. ***Figure 18.9*** $CaSO_3(s)$ ***Figure 18.11*** $(168\ W/m^2)/(342\ W/m^2) = 0.49$; that is, about 50% of the total. (Keep in mind that the IR radiation absorbed by Earth's surface is not directly solar radiation.) ***Figure 18.13*** The increasing slope corresponds to an increasing *rate* of addition of CO_2 to the atmosphere, probably as a result of ever-increasing burning of fossil fuels worldwide. ***Figure 18.15*** Evaporation from sea water, evaporation from freshwater; evaporation and transpiration from land. ***Figure 18.16*** The variable that most affects the density of water in this case is the change in temperature. As the water grows colder, its density increases. ***Figure 18.19*** Water is the chemical species that is crossing the membrane, not the ions. The water flows oppositely to the normal flow in osmosis because of the application of high pressure. ***Figure 18.20*** To reduce concentrations of dissolved iron and manganese, remove H_2S and NH_3, and reduce bacterial levels.

Chapter 19

Figure 19.1 Yes, the potential energy of the eggs decreases as they fall. ***Figure 19.2*** Because the final volume would be less than twice the volume of Flask A, the final pressure would be greater than 0.5 atm. ***Figure 19.3*** The freezing of liquid water to ice is exothermic. ***Figure 19.4*** To be truly reversible, the temperature change δT must be infinitesimally small. ***Figure 19.8*** There are two other independent rotational motions of the H_2O molecule:

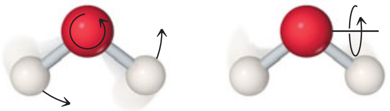

Figure 19.9 Ice, because it is the phase in which the molecules are held most rigidly ***Figure 19.11*** The decrease in the number of molecules due to the formation of new bonds. ***Figure 19.12*** During a phase change, the temperature remains constant but the entropy change can be large as molecules increase their degrees of freedom and motion. ***Figure 19.13*** Based on the three molecules shown, the addition of each C increases $S°$ by 40–45 J/mol-K. Based on this observation, we would predict that $S°(C_4H_{10})$ would 310–315 J/mol-K. Appendix C confirms that this is a good prediction: $S°(C_4H_{10}) = 310.0$ J/mol-K. ***Figure 19.14*** Spontaneous ***Figure 19.15*** If we plot progress of the reaction versus free energy, equilibrium is at a minimum point in free energy, as shown in the figure. In that sense, the reaction runs "downhill" until it reaches that minimum point.

Chapter 20

Figure 20.1 (a) The bubbling is caused by the hydrogen gas formed in the reaction. (b) The reaction is exothermic, and the heat causes the formation of steam. ***Figure 20.2*** The permanganate, MnO_4^-, is reduced, as the half-reactions in the text show. The oxalate ion, $C_2O_4^{2-}$, acts as the reducing agent. ***Figure 20.3*** The blue color is due to $Cu^{2+}(aq)$. As this ion is reduced, forming $Cu(s)$, its concentration decreases and the blue color fades. ***Figure 20.4*** The Zn is oxidized and, therefore, serves as the anode of the cell. ***Figure 20.5*** The electrical balance is maintained in two ways: Anions migrate into the half-cell, and cations migrate out. ***Figure 20.9*** As the cell operates, H^+ is reduced to H_2 in the cathode half-cell. As H^+ is depleted, the positive Na^+ ions are drawn into the half-cell to maintain electrical balance in the solution. ***Figure 20.11*** Yes. ***Figure 20.13*** The variable n is the number of moles of electrons transferred in the process. ***Figure 20.14*** The $Ni^{2+}(aq)$ ions and the cations in the salt bridge migrate toward the cathode. The $NO_3^-(aq)$ ions and the anions in the salt bridge migrate toward the anode. ***Figure 20.19*** The cathode consists of $PbO_2(s)$. Because each oxygen has an oxidation state of -2, lead must have an oxidation state of $+4$ in this compound. ***Figure 20.20*** Zn ***Figure 20.21*** Co^{3+}. The oxidation number increases as the battery charges ***Figure 20.24*** $O_2(g) + 4\,H^+ + 4\,e^- \longrightarrow 2\,H_2O(g)$ ***Figure 20.25*** The oxidizing agent of $O_2(g)$ from the air ***Figure 20.29*** 0 V

Chapter 21

Figure 21.2 From Figure 21.2 we see that the belt of stability for a nucleus containing 70 protons lies at approximately 102 neutrons. ***Figure 21.4*** Only three of the elements with an even number of protons have fewer than three isotopes: He, Be, and C. Note that these three elements are the lightest elements that have an even atomic number. Because they are so light, any change in the number of neutrons will change the neutron/proton ratio significantly. This helps to explain why they do not have more stable isotopes. None of the elements in Figure 21.4 that have an odd number of protons have more than two stable isotopes. ***Figure 21.6*** 6.25 g. After one half-life, the amount of the radioactive material will have dropped to 25.0 g. After two half-lives, it will have dropped to 12.5 g. After three half-lives, it will have dropped to 6.25 g. ***Figure 21.7*** Plants convert $^{14}CO_2$ to ^{14}C-containing sugars via photosynthesis. When mammals eat the plants, they metabolize the sugars, thereby incorporating ^{14}C in their bodies. ***Figure 21.8*** Gamma rays. Both X rays and gamma rays consist of high-energy electromagnetic radiation, whereas alpha and beta rays are streams of particles. ***Figure 21.9*** Ionization energy. Detection depends on the ability of the radiation to cause ionization of the gas atoms. ***Figure 21.13*** The mass numbers are equal on both sides. Remember that this does not mean that mass is conserved—mass is lost during the reaction, which appears as energy released. ***Figure 21.14*** 16. Each of the eight neutrons would split another uranium-235 nucleus, releasing two more neutrons. ***Figure 21.15*** Critical without being supercritical so that the release of energy is controlled. ***Figure 21.19*** Because large quantities of water are needed to condense the secondary coolant once it passes through the turbine. ***Figure 21.23*** Alpha rays are less dangerous when outside the body because they cannot penetrate the skin. However, once inside the body they can do great harm to any cells that are nearby.

Chapter 22

Figure 22.5 Beaker on the right is warmer. ***Figure 22.6*** HF is the most stable, SbH_3 the least stable. ***Figure 22.8*** More soluble in CCl_4 — the colors are deeper. ***Figure 22.9*** CF_2 ***Figure 22.10*** Redox reactions: The halides are being oxidized. ***Figure 22.13*** No ***Figure 22.15*** Based on this structure—yes, it would have a dipole moment. In fact, if you look it up, hydrogen peroxide's dipole moment is larger than water's! ***Figure 22.20*** They have been converted into water. ***Figure 22.21*** Formally they could both be $+2$. If we consider that the central sulfur is like SO_4^{2-}, however, then the central sulfur would be $+6$, like SO_4^{2-}, and then the terminal sulfur would be -2. ***Figure 22.22*** Nitrite ***Figure 22.23*** Longer. (There is a triple bond in N_2.) ***Figure 22.25*** The NO double bond ***Figure 22.27*** In both compounds the electron domains around the P atoms are tetrahedral. In P_4O_{10} all the electron domains around the P atoms are bonding. In P_4O_6 one of the electron domains about each P atom is nonbonding. ***Figure 22.32*** The minimum temperature should be the melting point of silicon; the temperature of the heating coil should not be so high that the silicon rod starts to melt outside the zone of the heating coil.

Chapter 23

Figure 23.3 No. The radius decreases first and then flattens out before increasing on moving past group 8B, while the effective nuclear charge increases steadily on moving left to right across the transition metal series. ***Figure 23.4*** Zn^{2+}. ***Figure 23.5*** The 4*s* orbitals are always empty in transition metal ions, so all of the ions shown in this table have empty 4*s* orbitals. The 3*d* orbitals are only empty for those ions that have lost all of their valence electrons: Sc^{3+}, Ti^{4+}, V^{5+}, Cr^{6+} and Mn^{7+}. ***Figure 23.6*** The electron spins would tend to align with the direction of the magnetic field. ***Figure 23.8*** No. If you start with a chloride ion on one vertex of the octahedron and then generate structures by placing the second chloride ion on any of the other five vertices you will get one complex that is the *trans* isomer and four complexes that are equivalent to the *cis* isomer shown in this figure. ***Figure 23.9*** $[Fe(H_2O)_6]^{3+}(aq) + SCN^-(aq) \longrightarrow [Fe(H_2O)_5(SCN)]^{2+}(aq) + H_2O(l)$ ***Figure 23.10*** The solid wedge represents a bond coming out of the plane of the page. The dashed wedge represents a bond that is going into the plane of the page. ***Figure 23.13*** Four for both (assuming no other ligands coordinate to the metal). ***Figure 23.15*** The coordination number is 6. Five nitrogen atoms (four from the heme and one from the protein) and one oxygen atom (from the O_2 molecule) coordinate iron. ***Figure 23.16*** The peak at 660 nm. ***Figure 23.20*** $[Fe(NH_3)_5(NO_2)]^{2+}$and pentaamminenitroiron(III) ion for the complex on the left. $[Fe(NH_3)_5(ONO)]^{2+}$ and pentaamminenitritoiron(III) ion for the complex on the right. ***Figure 23.21*** The *cis* isomer. ***Figure 23.24*** Larger, since ammonia can displace water. ***Figure 23.26*** The peak would stay in the same position in terms of wavelength, but its absorbance would decrease. ***Figure 23.28*** $d_{x^2-y^2}$ and d_{z^2}. ***Figure 23.29*** Convert the wavelength of light, 495 nm, into energy in joules using the relationship $E = hc/\lambda$. ***Figure 23.30*** The absorption peak would shift to shorter wavelengths absorbing green light and the color of the complex ion would become red. An even larger shift would move the absorption peak into the blue region of the spectrum and the color would become orange. ***Figure 23.34*** Only the $d_{x^2-y^2}$ orbital points directly at the ligands.

Chapter 24

Figure 24.1 Tetrahedral ***Figure 24.2*** The OH group is polar whereas the CH_3 group is nonpolar. Hence, adding CH_3 will (a) reduce the substance's solubility in polar solvents and (b) increase its solubility in nonpolar solvents. ***Figure 24.5*** C_nH_{2n}, because there are no CH_3 groups, each carbon has two hydrogens. ***Figure 24.7*** Just one ***Figure 24.9*** Intermediates are minima and transition states are maxima on energy profiles. ***Figure 24.13*** Both lactic acid and citric acid ***Figure 24.14*** No, because there are not four different groups around any carbon ***Figure 24.17*** Those labeled "basic amino acids," which have basic side groups that are protonated at pH 7 ***Figure 24.18*** Two. ***Figure 24.24*** The long hydrocarbon chains, which are nonpolar ***Figure 24.26*** The polar parts of the phospholipids seek to interact with water whereas the nonpolar parts seek to interact with other nonpolar substances and to avoid water. ***Figure 24.28*** Negatively charged, because of the charge on the phosphate groups. ***Figure 24.30*** GC because each base has three hydrogen bonding sites, whereas there are only two in AT.

ANSWERS TO SELECTED PRACTICE EXERCISES

Chapter 1

Sample Exercise 1.1
Practice Exercise 2: It is a compound because it has constant composition and can be separated into several elements.

Sample Exercise 1.2
Practice Exercise 2: **(a)** 10^{12} pm, **(b)** 6.0 km, **(c)** 4.22×10^{-3} g, **(d)** 0.00422 g.

Sample Exercise 1.3
Practice Exercise 2: **(a)** 261.7 K, **(b)** 11.3 °F

Sample Exercise 1.4
Practice Exercise 2: **(a)** $8.96\ \text{g/cm}^3$, **(b)** 19.0 mL, **(c)** 340 g.

Sample Exercise 1.5
Practice Exercise 2: Five, as in the measurement 24.995 g, the uncertainty being in the third decimal place.

Sample Exercise 1.6
Practice Exercise 2: No. The number of feet in a mile is a defined quantity and is therefore exact, but the distance represented by one foot is not exact, although it is known to high accuracy.

Sample Exercise 1.7
Practice Exercise 2: **(a)** four, **(b)** two, **(c)** three.

Sample Exercise 1.8
Practice Exercise 2: 9.52 m/s (three significant figures).

Sample Exercise 1.9
Practice Exercise 2: No. Even though the mass of the gas would then be known to four significant figures, the volume of the container would still be known to only three.

Sample Exercise 1.10
Practice Exercise 2: 804.7 km

Sample Exercise 1.11
Practice Exercise 2: 12 km/L.

Sample Exercise 1.12
Practice Exercise 2: 1.2×10^4 ft.

Sample Exercise 1.13
Practice Exercise 2: 832 g

Chapter 2

Sample Exercise 2.1
Practice Exercise 2: **(a)** 154 pm, **(b)** 1.3×10^6 C atoms

Sample Exercise 2.2
Practice Exercise 2: **(a)** 56 protons, 56 electrons, and 82 neutrons, **(b)** 15 protons, 15 electrons, and 16 neutrons.

Sample Exercise 2.3
Practice Exercise 2: $^{208}_{82}\text{Pb}$

Sample Exercise 2.4
Practice Exercise 2: 28.09 amu

Sample Exercise 2.5
Practice Exercise 2: Na, atomic number 11, is a metal; Br, atomic number 35, is a nonmetal.

Sample Exercise 2.6
Practice Exercise 2: B_5H_7

Sample Exercise 2.7
Practice Exercise 2: 34 protons, 45 neutrons, and 36 electrons

Sample Exercise 2.8
Practice Exercise 2: **(a)** $3+$, **(b)** $1-$

Sample Exercise 2.9
Practice Exercise 2: **(a)** Rb is from group 1, and readily loses one electron to attain the electron configuration of the nearest noble gas element, Kr. **(b)** Nitrogen and the halogens are all nonmetallic elements, which form molecular compounds with one another. **(c)** Krypton, Kr, is a noble gas element and is chemically inactive except under special conditions. **(d)** Na and K are both from group 1 and adjacent to one another in the periodic table. They would be expected to behave very similarly. **(e)** Calcium is an active metal and readily loses two electrons to attain the noble gas configuration of Ar.

Sample Exercise 2.10
Practice Exercise 2: **(a)** Na_3PO_4, **(b)** $ZnSO_4$, **(c)** $Fe_2(CO_3)_3$

Sample Exercise 2.11
Practice Exercise 2: BrO^- and BrO_2^-

Sample Exercise 2.12
Practice Exercise 2: **(a)** ammonium bromide, **(b)** chromium(III) oxide, **(c)** cobalt(II) nitrate

Sample Exercise 2.13
Practice Exercise 2: **(a)** HBr, **(b)** H_2CO_3

Sample Exercise 2.14
Practice Exercise 2: **(a)** $SiBr_4$, **(b)** S_2Cl_2, **(c)** P_2O_6.

Sample Exercise 2.15
Practice Exercise 2: No, they are not isomers because they have different molecular formulas. Butane is C_4H_{10}, whereas cyclobutane is C_4H_8.

Chapter 3

Sample Exercise 3.1
Practice Exercise 2: **(a)** $C_2H_4 + 3\,O_2 \longrightarrow 2\,CO_2 + 2\,H_2O$. **(b)** Nine O_2 molecules

Sample Exercise 3.2
Practice Exercise 2: **(a)** 4, 3, 2; **(b)** 2, 6, 2, 3; **(c)** 1, 2, 1, 1, 1

Sample Exercise 3.3
Practice Exercise 2: **(a)** $HgS(s) \longrightarrow Hg(l) + S(s)$, **(b)** $4\,Al(s) + 3\,O_2(g) \longrightarrow 2\,Al_2O_3(s)$

Sample Exercise 3.4
Practice Exercise 2: $C_2H_5OH(l) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 3\,H_2O(g)$

Sample Exercise 3.5
Practice Exercise 2: **(a)** 78.0 amu, **(b)** 32.0 amu, **(c)** 211.0 amu

Sample Exercise 3.6
Practice Exercise 2: 16.1%

Sample Exercise 3.7
Practice Exercise 2: 1 mol H_2O (6×10^{23} O atoms) $<$ 3×10^{23} molecules O_3 (9×10^{23} O atoms) $<$ 1 mol CO_2(12×10^{23} O atoms)

Sample Exercise 3.8
Practice Exercise 2: **(a)** 9.0×10^{23}, **(b)** 2.71×10^{24}

Sample Exercise 3.9
Practice Exercise 2: 164.1 g/mol

Sample Exercise 3.10
Practice Exercise 2: 55.5 mol H_2O.

Sample Exercise 3.11
Practice Exercise 2: **(a)** 6.0 g, **(b)** 8.29 g.

Sample Exercise 3.12
Practice Exercise 2: **(a)** 4.01×10^{22} molecules HNO_3, **(b)** 1.20×10^{23} atoms O

Sample Exercise 3.13
Practice Exercise 2: C_4H_4O

Sample Exercise 3.14
Practice Exercise 2: **(a)** CH_3O, **(b)** $C_2H_6O_2$

Sample Exercise 3.15
Practice Exercise 2: **(a)** C_3H_6O, **(b)** $C_6H_{12}O_2$

Sample Exercise 3.16
Practice Exercise 2: 1.77 g

Sample Exercise 3.17
Practice Exercise 2: 26.5 g

Sample Exercise 3.18
Practice Exercise 2: **(a)** Al, **(b)** 1.50 mol, **(c)** 0.75 mol Cl_2

Sample Exercise 3.19
Practice Exercise 2: **(a)** $AgNO_3$, **(b)** 1.59 g, **(c)** 1.39 g, **(d)** 1.52 g Zn

Sample Exercise 3.20
Practice Exercise 2: **(a)** 105 g Fe, **(b)** 83.7%

Chapter 4

Sample Exercise 4.1
Practice Exercise 2: **(a)** 6, **(b)** 12, **(c)** 2, **(d)** 9

Sample Exercise 4.2
Practice Exercise 2: **(a)** insoluble, **(b)** soluble, **(c)** soluble

Sample Exercise 4.3
Practice Exercise 2: **(a)** $Fe(OH)_3$, **(b)** $Fe_2(SO_4)_3(aq) + 6\,LiOH(aq) \longrightarrow 2\,Fe(OH)_3(s) + 3\,Li_2SO_4(aq)$

Sample Exercise 4.4
Practice Exercise 2: $3\,Ag^+(aq) + PO_4^{3-}(aq) \longrightarrow Ag_3PO_4(s)$

Sample Exercise 4.5
Practice Exercise 2: The diagram would show 10 Na^+ ions, 2 OH^- ions, 8 Y^- ions, and 8 H_2O molecules.

Sample Exercise 4.6
Practice Exercise 2: $C_6H_6O_6$ (nonelectrolyte) < CH_3COOH (weak electrolyte, existing mainly in the form of molecules with few ions) < $NaCH_3COO$ (strong electrolyte that provides two ions, Na^+ and CH_3COO^-) < $Ca(NO_3)_2$ (strong electrolyte that provides three ions, Ca^{2+} and 2 NO_3^-)

Sample Exercise 4.7
Practice Exercise 2:
(a) $H_3PO_3(aq) + 3\,KOH(aq) \longrightarrow 3\,H_2O(l) + K_3PO_3(aq)$,
(b) $H_3PO_3(aq) + 3\,OH^-(aq) \longrightarrow 3\,H_2O(l) + PO_3^{3-}(aq)$.
(H_3PO_3 is a weak acid and therefore a weak electrolyte, whereas KOH, a strong base, and K_3PO_3, an ionic compound, are strong electrolytes.)

Sample Exercise 4.8
Practice Exercise 2: **(a)** +5, **(b)** −1, **(c)** +6, **(d)** +4, **(e)** −1

Sample Exercise 4.9
Practice Exercise 2:
(a) $Mg(s) + CoSO_4(aq) \longrightarrow MgSO_4(aq) + Co(s)$;
$Mg(s) + Co^{2+}(aq) \longrightarrow Mg^{2+}(aq) + Co(s)$,
(b) Mg is oxidized and Co^{2+} is reduced.

Sample Exercise 4.10
Practice Exercise 2: Zn and Fe

Sample Exercise 4.11
Practice Exercise 2: 0.278 *M*

Sample Exercise 4.12
Practice Exercise 2: 0.030 *M*

Sample Exercise 4.13
Practice Exercise 2: **(a)** 1.1 g, **(b)** 76 mL

Sample Exercise 4.14
Practice Exercise 2: **(a)** 0.0200 L = 20.0 mL, **(b)** 5.0 mL, **(c)** 0.40 *M*

Sample Exercise 4.15
Practice Exercise 2: **(a)** 0.240 g, **(b)** 0.400 L

Sample Exercise 4.16
Practice Exercise 2: 0.210 *M*

Sample Exercise 4.17
Practice Exercise 2: **(a)** 1.057×10^{-3} mol MnO_4^-, **(b)** 5.286×10^{-3} mol Fe^{2+}, **(c)** 0.2952 g, **(d)** 33.21%

Chapter 5

Sample Exercise 5.1
Practice Exercise 2: **(a)** 1.4×10^{-20} J, **(b)** 8.4×10^{3} J

Sample Exercise 5.2
Practice Exercise 2: +55 J

Sample Exercise 5.3
Practice Exercise 2: 0.69 L-atm = 70 J

Sample Exercise 5.4
Practice Exercise 2: In order to solidify, the gold must cool to below its melting temperature. It cools by transferring heat to its surroundings. The air around the sample would feel hot because heat is transferred to it from the molten gold, meaning the process is exothermic. (You may notice that solidification of a liquid is the reverse of the melting we analyzed in the exercise. As we will see, reversing the direction of a process changes the sign of the heat transferred.)

Sample Exercise 5.5
Practice Exercise 2: −14.4 kJ

Sample Exercise 5.6
Practice Exercise 2: **(a)** 4.9×10^{5} J, **(b)** 11 K decrease = 11 °C decrease

Sample Exercise 5.7
Practice Exercise 2: −68,000 J/mol = −68 kJ/mol

Sample Exercise 5.8
Practice Exercise 2: **(a)** −15.2 kJ/g, **(b)** −1370 kJ/mol

Sample Exercise 5.9
Practice Exercise 2: +1.9 kJ

Sample Exercise 5.10
Practice Exercise 2: −304.1 kJ

Sample Exercise 5.11
Practice Exercise 2: $C(graphite) + 2\,Cl_2(g) \longrightarrow CCl_4(l)$; $\Delta H_f^\circ = -106.7$ kJ/mol.

Sample Exercise 5.12
Practice Exercise 2: −1367 kJ

Sample Exercise 5.13
Practice Exercise 2: −156.1 kJ/mol

Sample Exercise 5.14
Practice Exercise 2: **(a)** 15 kJ/g, **(b)** 100 min

Chapter 6

Sample Exercise 6.1
Practice Exercise 2: The expanded visible-light portion of Figure 6.4 tells you that red light has a longer wavelength than blue light. The lower wave has the longer wavelength (lower frequency) and would be the red light.

Sample Exercise 6.2
Practice Exercise 2: **(a)** $1.43 \times 10^{14}\ s^{-1}$, **(b)** 2.899 m

Sample Exercise 6.3
Practice Exercise 2: **(a)** 3.11×10^{-19} J, **(b)** 0.16 J, **(c)** 4.2×10^{16} photons

Sample Exercise 6.4
Practice Exercise 2: **(a)** $\Delta E < 0$, photon emitted, **(b)** $\Delta E > 0$, photon absorbed

Sample Exercise 6.5
Practice Exercise 2: 7.86×10^2 m/s

Sample Exercise 6.6
Practice Exercise 2: **(a)** 5*p*; **(b)** 3; **(c)** 1, 0, −1

Sample Exercise 6.7
Practice Exercise 2: **(a)** $1s^2 2s^2 2p^6 3s^2 3p^2$, **(b)** two

Sample Exercise 6.8
Practice Exercise 2: group 4A

Sample Exercise 6.9
Practice Exercise 2: **(a)** $[Ar]4s^2 3d^7$ or $[Ar]3d^7 4s^2$, **(b)** $[Kr]5s^2 4d^{10} 5p^1$ or $[Kr]4d^{10} 5s^2 5p^1$

Chapter 7

Sample Exercise 7.1
Practice Exercise 2: P—Br

Sample Exercise 7.2
Practice Exercise 2: C < Be < Ca < K

Sample Exercise 7.3
Practice Exercise 2: S^{2-}

Sample Exercise 7.4
Practice Exercise 2: Cs^+

Sample Exercise 7.5
Practice Exercise 2: Ca

Sample Exercise 7.6
Practice Exercise 2: Al lowest, C highest

Sample Exercise 7.7
Practice Exercise 2: **(a)** >

Sample Exercise 7.8
Practice Exercise 2:
$CuO(s) + H_2SO_4(aq) \longrightarrow CuSO_4(aq) + H_2O(l)$

Sample Exercise 7.9
Practice Exercise 2: $P_4O_6(s) + 6\ H_2O(l) \longrightarrow 4\ H_3PO_3(aq)$

Sample Exercise 7.10
Practice Exercise 2: $2K(s) + S(s) \longrightarrow K_2S(s)$

Chapter 8

Sample Exercise 8.1
Practice Exercise 2: ZrO_2

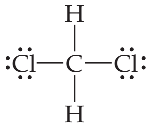
Sample Exercise 8.2
Practice Exercise 2: Mg^{2+} and N^{3-}

Sample Exercise 8.3
Practice Exercise 2: They both show 8 valence electrons; methane has 4 bonding pairs and neon has 4 nonbonding pairs

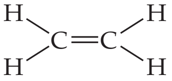
Sample Exercise 8.4
Practice Exercise 2: Se—Cl

Sample Exercise 8.5
Practice Exercise 2: **(a)** F, **(b)** 0.11−

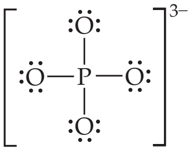
Sample Exercise 8.6
Practice Exercise 2: **(a)** 20, **(b)**



Sample Exercise 8.7
Practice Exercise 2: **(a)** $[:N\equiv O:]^+$, **(b)**

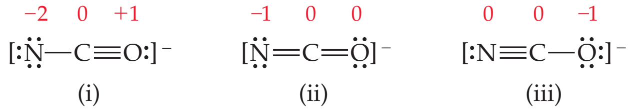


Sample Exercise 8.8
Practice Exercise 2: **(a)** $[:\ddot{O}-\ddot{Cl}-\ddot{O}:]^-$ **(b)**



Sample Exercise 8.9
Practice Exercise 2:

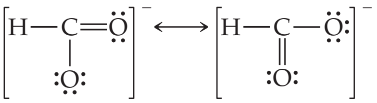
(a)



(b) Structure (iii), which places a negative charge on oxygen, the most electronegative element in the ion, is the dominant Lewis structure.

Sample Exercise 8.10

Practice Exercise 2:



Sample Exercise 8.11
Practice Exercise 2:
(a) C, **(b)** $:\ddot{F}-\ddot{Xe}-\ddot{F}:$

Sample Exercise 8.12
Practice Exercise 2: −86 kJ

Chapter 9

Sample Exercise 9.1
Practice Exercise 2: **(a)** tetrahedral, bent; **(b)** trigonal planar, trigonal planar

Sample Exercise 9.2
Practice Exercise 2: **(a)** trigonal bipyramidal, T-shaped; **(b)** trigonal bipyramidal, trigonal bipyramidal.

Sample Exercise 9.3
Practice Exercise 2: 109.5°, 180°

Sample Exercise 9.4
Practice Exercise 2: **(a)** polar because polar bonds are arranged in a seesaw geometry, **(b)** nonpolar because polar bonds are arranged in a tetrahedral geometry

Sample Exercise 9.5
Practice Exercise 2: tetrahedral, sp^3

Sample Exercise 9.6
Practice Exercise 2: **(a)** approximately 109° around the left C and 180° around the right C; **(b)** sp^3, sp; **(c)** five σ bonds and two π bonds

Sample Exercise 9.7
Practice Exercise 2: SO_2 and SO_3, as indicated by the presence of two or more resonance structures involving π bonding for each of these molecules.

Sample Exercise 9.8
Practice Exercise 2: $\sigma_{1s}{}^2\sigma_{1s}^{\star 1}$; $\frac{1}{2}$

Sample Exercise 9.9
Practice Exercise 2: **(a)** diamagnetic, 1; **(b)** diamagnetic, 3

Chapter 10

Sample Exercise 10.1
Practice Exercise 2: (D) 1.6 M

Sample Exercise 10.2
Practice Exercise 2: 807.3 torr

Sample Exercise 10.3
Practice Exercise 2: 5.30×10^3 L

Sample Exercise 10.4
Practice Exercise 2: 2.0 atm

Sample Exercise 10.5
Practice Exercise 2: $3.83 \times 10^3\ m^3$

Sample Exercise 10.6
Practice Exercise 2: 27 °C

Sample Exercise 10.7
Practice Exercise 2: 5.9 g/L

Sample Exercise 10.8
Practice Exercise 2: 29.0 g/mol

Sample Exercise 10.9
Practice Exercise 2: 14.8 L

Sample Exercise 10.10
Practice Exercise 2: 2.86 atm

Sample Exercise 10.11
Practice Exercise 2: 1.0×10^3 torr N_2, 1.5×10^2 torr Ar, and 73 torr CH_4

Sample Exercise 10.12
Practice Exercise 2: **(a)** increases, **(b)** no effect, **(c)** no effect

Sample Exercise 10.13
Practice Exercise 2: 1.36×10^3 m/s

Sample Exercise 10.14
Practice Exercise 2: $r_{N_2}/r_{O_2} = 1.07$

Sample Exercise 10.15
Practice Exercise 2: **(a)** 7.472 atm, **(b)** 7.181 atm

Chapter 11

Sample Exercise 11.1
Practice Exercise 2: chloramine, NHCl

Sample Exercise 11.2
Practice Exercise 2: **(a)** CH_3CH_3 has only dispersion forces, whereas the other two substances have both dispersion forces and hydrogen bonds, **(b)** CH_3CH_2OH

Sample Exercise 11.3
Practice Exercise 2: $-20.9\text{ kJ} - 33.4\text{ kJ} - 6.09\text{ kJ} = -60.4\text{ kJ}$

Sample Exercise 11.4
Practice Exercise 2: about 340 torr (0.45 atm)

Sample Exercise 11.5
Practice Exercise 2: **(a)** −162 °C; **(b)** It sublimes whenever the pressure is less than 0.1 atm; **(c)** The highest temperature at which a liquid can exist is defined by the critical temperature. So we do not expect to find liquid methane when the temperature is higher than −80 °C.

Sample Exercise 11.6
Practice Exercise 2: Because rotation can occur about carbon–carbon single bonds, molecules whose backbone consists predominantly of C—C single bonds are too flexible; the molecules tend to coil in random ways and, thus, are not rodlike.

Chapter 12

Sample Exercise 12.1
Practice Exercise 2: 0.68 or 68%

Sample Exercise 12.2
Practice Exercise 2: $a = 4.02$ Å and density $= 4.31\ g/cm^3$

Sample Exercise 12.3
Practice Exercise 2: smaller.

Sample Exercise 12.4
Practice Exercise 2: A group 5A element could be used to replace Se.

Chapter 13

Sample Exercise 13.1
Practice Exercise 2: $C_5H_{12} < C_5H_{11}Cl < C_5H_{11}OH < C_5H_{10}(OH)_2$ (in order of increasing polarity and hydrogen-bonding ability)

Sample Exercise 13.2
Practice Exercise 2: $1.0 \times 10^{-5}\ M$

Sample Exercise 13.3
Practice Exercise 2: 90.5 g of NaOCl

Sample Exercise 13.4
Practice Exercise 2: 0.670 m

Sample Exercise 13.5
Practice Exercise 2: **(a)** 9.00×10^{-3}, **(b)** 0.505 m

Sample Exercise 13.6
Practice Exercise 2: **(a)** 10.9 m, **(b)** $X_{C_3H_8O_3} = 0.163$, **(c)** 5.97 M

Sample Exercise 13.7
Practice Exercise 2: 0.290

Sample Exercise 13.8
Practice Exercise 2: −65.6 °C

Sample Exercise 13.9
Practice Exercise 2: 0.048 atm

Sample Exercise 13.10
Practice Exercise 2: 110 g/mol

Sample Exercise 13.11
Practice Exercise 2: 4.20×10^4 g/mol

Chapter 14

Sample Exercise 14.1
Practice Exercise 2: $1.8 \times 10^{-2}\ M/s$

Sample Exercise 14.2
Practice Exercise 2: $1.1 \times 10^{-4}\ M/s$

Sample Exercise 14.3
Practice Exercise 2: **(a)** $8.4 \times 10^{-7}\ M/s$, **(b)** $2.1 \times 10^{-7}\ M/s$

Sample Exercise 14.4
Practice Exercise 2: $2 = 3 < 1$

Sample Exercise 14.5
Practice Exercise 2: **(a)** 1, **(b)** $M^{-1}\,s^{-1}$.

Sample Exercise 14.6
Practice Exercise 2: **(a)** $\text{rate} = k[NO]^2[H_2]$, **(b)** $k = 1.2\,M^{-2}\,s^{-1}$ **(c)** $\text{rate} = 4.5 \times 10^{-4}\,M/s$

Sample Exercise 14.7
Practice Exercise 2: 51 torr

Sample Exercise 14.8
Practice Exercise 2: $[NO_2] = 1.00 \times 10^{-3}\,M$

Sample Exercise 14.9
Practice Exercise 2: **(a)** $0.478\text{ yr} = 1.51 \times 10^7\text{ s}$, **(b)** it takes two half-lives, $2(0.478\text{ yr}) = 0.956\text{ yr}$

Sample Exercise 14.10
Practice Exercise 2: $2 < 1 < 3$ because, if you approach the barrier from the right, the E_a values are 40 kJ/mol for reverse reaction 2, 25 kJ/molfor reverse reaction 1, and 15 kJ/mol for reverse reaction 3.

Sample Exercise 14.11
Practice Exercise 2: $2 \times 10^{13}\,s^{-1}$

Sample Exercise 14.12
Practice Exercise 2: **(a)** Yes, the two equations add to yield the equation for the reaction. **(b)** The first elementary reaction is unimolecular, and the second one is bimolecular. **(c)** $Mo(CO)_5$.

Sample Exercise 14.13
Practice Exercise 2: **(a)** $\text{Rate} = k[NO]^2[Br_2]$, **(b)** No, because termolecular reactions are very rare.

Sample Exercise 14.14
Practice Exercise 2: Because the rate law conforms to the molecularity of the first step, the first step must be the rate-determining step. The second step must be much faster than the first one.

Sample Exercise 14.15
Practice Exercise 2: $[Br] = \left(\dfrac{k_1}{k_{-1}}[Br_2]\right)^{1/2}$

Chapter 15

Sample Exercise 15.1
Practice Exercise 2: **(a)** $K_c = \dfrac{[HI]^2}{[H_2][I_2]}$, **(b)** $K_c = \dfrac{[CdBr_4{}^{2-}]}{[Cd^{2+}][Br^-]^4}$

Sample Exercise 15.2
Practice Exercise 2: 0.335

Sample Exercise 15.3
Practice Exercise 2: At the lower temperature because K_p is larger at the lower temperature

Sample Exercise 15.4
Practice Exercise 2: $\dfrac{(54.0)^3}{1.04 \times 10^{-4}} = 1.51 \times 10^9$

Sample Exercise 15.5
Practice Exercise 2:
(a) $K_c = \dfrac{[Cr^{3+}]}{[Ag^+]^3}$, **(b)** $K_p = \dfrac{(P_{H_2})^4}{(P_{H_2O})^4}$

Sample Exercise 15.6
Practice Exercise 2: $H_2(g)$

Sample Exercise 15.7
Practice Exercise 2: 1.79×10^{-5}

Sample Exercise 15.8
Practice Exercise 2: 33

Sample Exercise 15.9
Practice Exercise 2: $Q_p = 16$; $Q_p > K_p$, and so the reaction will proceed from right to left, forming more SO_3.

Sample Exercise 15.10
Practice Exercise 2: 1.22 atm

Sample Exercise 15.11
Practice Exercise 2: $P_{PCl_5} = 0.967$ atm, $P_{PCl_3} = P_{Cl_2} = 0.693$ atm

Sample Exercise 15.12
Practice Exercise 2: **(a)** right, **(b)** left, **(c)** right, **(d)** left

Sample Exercise 15.13
Practice Exercise 2: $\Delta H^\circ = 508.3$ kJ; the equilibrium constant will increase with increasing temperature.

Chapter 16

Sample Exercise 16.1
Practice Exercise 2: H_2SO_3, HF, $HPO_4{}^{2-}$, HCO^+

Sample Exercise 16.2
Practice Exercise 2: $O^{2-}(aq) + H_2O(l) \longrightarrow OH^-(aq) + OH^-(aq)$. The OH^- is both the conjugate acid of O^{2-} and the conjugate base of H_2O.

Sample Exercise 16.3
Practice Exercise 2: **(a)** left, **(b)** right

Sample Exercise 16.4
Practice Exercise 2: **(a)** basic, **(b)** neutral, **(c)** acidic

Sample Exercise 16.5
Practice Exercise 2: **(a)** $5 \times 10^{-9}\,M$, **(b)** $1.0 \times 10^{-7}\,M$, **(c)** $7.1 \times 10^{-9}\,M$

Sample Exercise 16.6
Practice Exercise 2: **(a)** 3.42, **(b)** $[H^+] = 5.3 \times 10^{-9}\,M$, so $\text{pH} = 8.28$

Sample Exercise 16.7
Practice Exercise 2: $[H^+] = 6.6 \times 10^{-10}$

Sample Exercise 16.8
Practice Exercise 2: $0.0046\,M$

Sample Exercise 16.9
Practice Exercise 2: **(a)** $7.8 \times 10^{-3}\,M$, **(b)** $2.4 \times 10^{-3}\,M$

Sample Exercise 16.10
Practice Exercise 2: 1.5×10^{-5}

Sample Exercise 16.11
Practice Exercise 2: 2.7%

Sample Exercise 16.12
Practice Exercise 2: 3.41

Sample Exercise 16.13
Practice Exercise 2: **(a)** 3.9%, **(b)** 12%

Sample Exercise 16.14
Practice Exercise 2: **(a)** $\text{pH} = 1.80$, **(b)** $[C_2O_4{}^{2-}] = 6.4 \times 10^{-5}\,M$

Sample Exercise 16.15
Practice Exercise 2: Methylamine (because it has the larger K_b value of the two amine bases in the list)

Sample Exercise 16.16
Practice Exercise 2: $0.12\,M$

Sample Exercise 16.17
Practice Exercise 2: **(a)** $PO_4{}^{3-}(K_b = 2.4 \times 10^{-2})$, **(b)** $K_b = 7.9 \times 10^{-10}$

Sample Exercise 16.18
Practice Exercise 2: **(a)** $Fe(NO_3)_3$, **(b)** KBr, **(c)** CH_3NH_3Cl, **(d)** NH_4NO_3

Sample Exercise 16.19
Practice Exercise 2: acidic

Sample Exercise 16.20
Practice Exercise 2: **(a)** HBr, **(b)** H_2S, **(c)** HNO_3, **(d)** H_2SO_3

Chapter 17

Sample Exercise 17.1
Practice Exercise 2: 3.42

Sample Exercise 17.2
Practice Exercise 2: $[HCOO^-] = 9.0 \times 10^{-5}$, pH $= 1.00$

Sample Exercise 17.3
Practice Exercise 2: 4.42

Sample Exercise 17.4
Practice Exercise 2: 4.62 (using quadratic).

Sample Exercise 17.5
Practice Exercise 2: 0.13 *M*

Sample Exercise 17.6
Practice Exercise 2: **(a)** 4.68, **(b)** 1.70

Sample Exercise 17.7
Practice Exercise 2: **(a)** 10.30, **(b)** 3.70

Sample Exercise 17.8
Practice Exercise 2: **(a)** 4.20, **(b)** 9.26

Sample Exercise 17.9
Practice Exercise 2: **(a)** 8.21, **(b)** 5.28

Sample Exercise 17.10
Practice Exercise 2: **(a)** $K_{sp} = [Ba^{2+}][CO_3^{2-}] = 5.0 \times 10^{-9}$, **(b)** $K_{sp} = [Ag^+]^2[SO_4^{2-}] = 1.5 \times 10^{-5}$

Sample Exercise 17.11
Practice Exercise 2: 1.6×10^{-12}

Sample Exercise 17.12
Practice Exercise 2: 9×10^{-6} mol/L

Sample Exercise 17.13
Practice Exercise 2: 4.0×10^{-10} *M*

Sample Exercise 17.14
Practice Exercise 2: **(a)** $CuS(s) + H^+(aq) \rightleftharpoons Cu^{2+}(aq) + HS^-(aq)$, **(b)** $Cu(N_3)_2(s) + 2H^+(aq) \rightleftharpoons Cu^{2+}(aq) + 2HN_3(aq)$

Sample Exercise 17.15
Practice Exercise 2: 1×10^{-16} *M*

Sample Exercise 17.16
Practice Exercise 2: Yes, CaF_2 precipitates because $Q = 4.6 \times 10^{-8}$ is larger than $K_{sp} = 3.9 \times 10^{-11}$

Sample Exercise 17.17
Practice Exercise 2: $Cu(OH)_2$ precipitates first, beginning when $[OH^-] > 1.5 \times 10^{-9}$ *M*. $Mg(OH)_2$ begins to precipitate when $[OH^-] > 1.9 \times 10^{-5}$ *M*.

Chapter 18

Sample Exercise 18.1
Practice Exercise 2: 3.0×10^{-3} torr

Sample Exercise 18.2
Practice Exercise 2: 127 nm

Chapter 19

Sample Exercise 19.1
Practice Exercise 2: No, the reverse process is spontaneous at this temperature.

Sample Exercise 19.2
Practice Exercise 2: −163 J/K

Sample Exercise 19.3
Practice Exercise 2: no

Sample Exercise 19.4
Practice Exercise 2: **(a)** 1 mol of $SO_2(g)$ at STP, **(b)** 2 mol of $NO_2(g)$ at STP

Sample Exercise 19.5
Practice Exercise 2: 180.39 J/K

Sample Exercise 19.6
Practice Exercise 2: $\Delta G^\circ = -14.7$ kJ; the reaction is spontaneous.

Sample Exercise 19.7
Practice Exercise 2: −800.7 kJ

Sample Exercise 19.8
Practice Exercise 2: More negative

Sample Exercise 19.9
Practice Exercise 2: **(a)** $\Delta H^\circ = -196.6$ kJ, $\Delta S^\circ = -189.6$ J/K; **(b)** $\Delta G^\circ = -120.8$ kJ

Sample Exercise 19.10
Practice Exercise 2: 330 K

Sample Exercise 19.11
Practice Exercise 2: −26.0 kJ/mol

Sample Exercise 19.12
Practice Exercise 2: $\Delta G^\circ = -106.4$ kJ/mol, $K = 4 \times 10^{18}$

Chapter 20

Sample Exercise 20.1
Practice Exercise 2: Al(*s*) is the reducing agent; $MnO_4^-(aq)$ is the oxidizing agent.

Sample Exercise 20.2
Practice Exercise 2: $Cu(s) + 4\,H^+(aq) + 2\,NO_3^-(aq) \longrightarrow Cu^{2+}(aq) + 2\,NO_2(g) + 2\,H_2O(l)$

Sample Exercise 20.3
Practice Exercise 2: $2\,Cr(OH)_3(s) + 6\,ClO^-(aq) \longrightarrow 2\,CrO_4^{2-}(aq) + 3\,Cl_2(g) + 2\,OH^-(aq) + 2\,H_2O(l)$

Sample Exercise 20.4
Practice Exercise 2: **(a)** The first reaction occurs at the anode and the second reaction at the cathode. **(b)** Zinc is oxidized to form Zn^{2+} as the reaction proceeds and therefore the zinc electrode loses mass. **(c)** The platinum electrode is not involved in the reaction and none of the products of the reaction at the cathode are solids, so the mass of platinum electrode does not change. **(d)** The platinum cathode is positive.

Sample Exercise 20.5
Practice Exercise 2: −0.40 V

Sample Exercise 20.6
Practice Exercise 2: 2.20 V

Sample Exercise 20.7
Practice Exercise 2:
(a) $Co \longrightarrow Co^{2+} + 2\,e^-$; **(b)** +0.499 V

Sample Exercise 20.8
Practice Exercise 2: $Al(s) > Fe(s) > I^-(aq)$

Sample Exercise 20.9
Practice Exercise 2: Reactions (b) and (c) are spontaneous.

Sample Exercise 20.10
Practice Exercise 2: +77 kJ/mol

Sample Exercise 20.11
Practice Exercise 2: It would increase.

Sample Exercise 20.12
Practice Exercise 2: pH $= 4.23$ (using data from Appendix E to obtain $E°$ to three significant figures)

Sample Exercise 20.13
Practice Exercise 2: **(a)** The anode is the half-cell in which $[Zn^{2+}] = 3.75 \times 10^{-4}\,M$. **(b)** The emf is 0.105 V.

Sample Exercise 20.14
Practice Exercise 2: **(a)** 30.2 g of Mg, **(b)** 3.97×10^3 s

Chapter 21

Sample Exercise 21.1
Practice Exercise 2: ${}^{212}_{84}Po$

Sample Exercise 21.2
Practice Exercise 2: ${}^{15}_{8}O \longrightarrow {}^{15}_{7}N + {}^{0}_{+1}e$

Sample Exercise 21.3
Practice Exercise 2:
(a) α emission, **(b)** β^- emission

Sample Exercise 21.4
Practice Exercise 2: ${}^{16}_{8}O(p, \alpha){}^{13}_{7}N$

Sample Exercise 21.5
Practice Exercise 2: 3.12%

Sample Exercise 21.6
Practice Exercise 2: 2200 yr

Sample Exercise 21.7
Practice Exercise 2: 15.1%

Sample Exercise 21.8
Practice Exercise 2: -3.19×10^{-3} g

Chapter 22

Sample Exercise 22.1
Practice Exercise 2: **(a)** Cs, **(b)** Cl, **(c)** C, **(d)** Sb

Sample Exercise 22.2
Practice Exercise 2: $NaH(s) + H_2O(l) \longrightarrow NaOH(aq) + H_2(g)$

Sample Exercise 22.3
Practice Exercise 2: trigonal bipyramidal, linear

Sample Exercise 22.4
Practice Exercise 2: $2\,Br^-(aq) + Cl_2(aq) \longrightarrow Br_2(aq) + 2\,Cl^-(aq)$

Sample Exercise 22.5
Practice Exercise 2: $NaI(s) + H_3PO_4(l) \longrightarrow NaH_2PO_4(s) + HI(g)$

Sample Exercise 22.6
Practice Exercise 2: $5\,N_2O_4(l) + 4\,N_2H_3CH_3(l) \longrightarrow 9\,N_2(g) + 4\,CO_2(g) + 12\,H_2O(g)$

Sample Exercise 22.7
Practice Exercise 2: 6−

Chapter 23

Sample Exercise 23.1
Practice Exercise 2: three: $[Co(H_2O)_6]^{2+}$ and two Cl^-

Sample Exercise 23.2
Practice Exercise 2: zero

Sample Exercise 23.3
Practice Exercise 2: **(a)** triamminetribromomolybdenum(IV) nitrate, **(b)** ammonium tetrabromocuprate(II), **(c)** $Na[Ru(H_2O)_2(C_2O_4)_2]$

Sample Exercise 23.4
Practice Exercise 2: two

Sample Exercise 23.5
Practice Exercise 2: No, because the complex is flat. This complex ion does, however, have geometric isomers (for example, the Cl and Br ligands could be cis or trans).

Sample Exercise 23.6
Practice Exercise 2: green

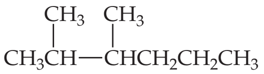
Sample Exercise 23.7
Practice Exercise 2: $[Co(NH_3)_5Cl]^{2+}$ is purple which means it must absorb light near the boundary between the yellow and green regions of the spectrum. $[Co(NH_3)_6]^{3+}$ is orange which means it absorbs blue light. Because yellow-green have a lower energy (longer wavelength) than blue photons Δ is smaller for $[Co(NH_3)_5Cl]^{2+}$. This prediction is consistent with the spectrochemical series because Cl^- ligands are at the low end of the spectrochemical series. Thus replacing NH_3 with Cl^- should make Δ smaller.

Sample Exercise 23.8
Practice Exercise 2: No it is not possible to have a diamagnetic complex with partially filled *d* orbitals if the complex is high spin, and all tetrahedral complexes are high spin.

Chapter 24

Sample Exercise 24.1
Practice Exercise 2: 2,4-dimethylpentane

Sample Exercise 24.2
Practice Exercise 2:

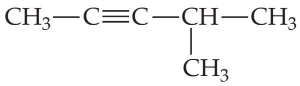


$$CH_3\overset{\overset{CH_3}{|}}{C}H{-}\overset{\overset{CH_3}{|}}{C}HCH_2CH_2CH_3$$

or $CH_3CH(CH_3)CH(CH_3)CH_2CH_2CH_3$

Sample Exercise 24.3
Practice Exercise 2: five (1-hexene, *cis*-2-hexene, *trans*-2-hexene, *cis*-3-hexene, *trans*-3-hexene)

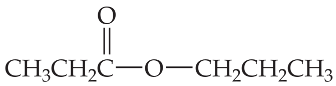
Sample Exercise 24.4
Practice Exercise 2:



$$CH_3{-}C{\equiv}C{-}\underset{\underset{CH_3}{|}}{C}H{-}CH_3$$

Sample Exercise 24.5
Practice Exercise 2: propene

Sample Exercise 24.6
Practice Exercise 2:



$$CH_3CH_2\overset{\overset{O}{\|}}{C}{-}O{-}CH_2CH_2CH_3$$

Sample Exercise 24.7
Practice Exercise 2: serylaspartic acid; Ser-Asp, SD

Sample Exercise 24.8
Practice Exercise 2: alcohol, ether

GLOSSARY

absolute zero The lowest attainable temperature; 0 K on the Kelvin scale and -273.15 °C on the Celsius scale. (Section 1.4)

absorption spectrum A pattern of variation in the amount of light absorbed by a sample as a function of wavelength. (Section 23.5)

accuracy A measure of how closely individual measurements agree with the correct value. (Section 1.5)

acid A substance that is able to donate a H^+ ion (a proton) and, hence, increases the concentration of $H^+(aq)$ when it dissolves in water. (Section 4.3)

acid-dissociation constant (K_a) An equilibrium constant that expresses the extent to which an acid transfers a proton to solvent water. (Section 16.6)

acidic anhydride (acidic oxide) An oxide that forms an acid when added to water; soluble nonmetal oxides are acidic anhydrides. (Section 22.5)

acidic oxide (acidic anhydride) An oxide that either reacts with a base to form a salt or with water to form an acid. (Section 22.5)

acid rain Rainwater that has become excessively acidic because of absorption of pollutant oxides, notably SO_3, produced by human activities. (Section 18.2)

actinide element Element in which the $5f$ orbitals are only partially occupied. (Section 6.8)

activated complex (transition state) The particular arrangement of atoms found at the top of the potential-energy barrier as a reaction proceeds from reactants to products. (Section 14.5)

activation energy (E_a) The minimum energy needed for reaction; the height of the energy barrier to formation of products. (Section 14.5)

active site Specific site on a heterogeneous catalyst or an enzyme where catalysis occurs. (Section 14.7)

activity The decay rate of a radioactive material, generally expressed as the number of disintegrations per unit time. (Section 21.4)

activity series A list of metals in order of decreasing ease of oxidation. (Section 4.4)

addition polymerization Polymerization that occurs through coupling of monomers with one another, with no other products formed in the reaction. (Section 12.8)

addition reaction A reaction in which a reagent adds to the two carbon atoms of a carbon–carbon multiple bond. (Section 24.3)

adsorption The binding of molecules to a surface. (Section 14.7)

alcohol An organic compound obtained by substituting a hydroxyl group $(-OH)$ for a hydrogen on a hydrocarbon. (Sections 2.9 and 24.4)

aldehyde An organic compound that contains a carbonyl group $(C{=}O)$ to which at least one hydrogen atom is attached. (Section 24.4)

alkali metals Members of group 1A in the periodic table. (Section 7.7)

alkaline earth metals Members of group 2A in the periodic table. (Section 7.7)

alkanes Compounds of carbon and hydrogen containing only carbon–carbon single bonds. (Sections 2.9 and 24.2)

alkenes Hydrocarbons containing one or more carbon–carbon double bonds. (Section 24.2)

alkyl group A group that is formed by removing a hydrogen atom from an alkane. (Section 25.3)

alkynes Hydrocarbons containing one or more carbon–carbon triple bonds. (Section 24.2)

alloy A substance that has the characteristic properties of a metal and contains more than one element. Often there is one principal metallic component, with other elements present in smaller amounts. Alloys may be homogeneous or heterogeneous. (Section 12.3)

alpha decay A type of radioactive decay in which an atomic nucleus emits an alpha particle and thereby transforms (or "decays") into an atom with a mass number 4 less and atomic number 2 less. (Section 21.1)

alpha (α) helix A protein structure in which the protein is coiled in the form of a helix with hydrogen bonds between $C{=}O$ and $N-H$ groups on adjacent turns. (Section 24.7)

alpha particles Particles that are identical to helium-4 nuclei, consisting of two protons and two neutrons, symbol ^4_2He or $^4_2\alpha$. (Section 21.1)

amide An organic compound that has an NR_2 group attached to a carbonyl. (Section 24.4)

amine A compound that has the general formula R_3N, where R may be H or a hydrocarbon group. (Section 16.7)

amino acid A carboxylic acid that contains an amino $(-NH_2)$ group attached to the carbon atom adjacent to the carboxylic acid $(-COOH)$ functional group. (Section 24.7)

amorphous solid A solid whose molecular arrangement lacks the regularly repeating long-range pattern of a crystal. (Section 12.2)

amphiprotic Refers to the capacity of a substance to either add or lose a proton (H^+). (Section 16.2)

amphoteric oxides and hydroxides Oxides and hydroxides that are only slightly soluble in water but that dissolve in either acidic or basic solutions. (Section 17.5)

angstrom A common non-SI unit of length, denoted Å, that is used to measure atomic dimensions: $1Å = 10^{-10}$ m. (Section 2.3)

anion A negatively charged ion. (Section 2.7)

anode An electrode at which oxidation occurs. (Section 20.3)

antibonding molecular orbital A molecular orbital in which electron density is concentrated outside the region between the two nuclei of bonded atoms. Such orbitals, designated as σ^* or π^*, are less stable (of higher energy) than bonding molecular orbitals. (Section 9.7)

antiferromagnetism A form of magnetism in which unpaired electron spins on adjacent sites point in opposite directions and cancel each other's effects. (Section 23.1)

aqueous solution A solution in which water is the solvent. (Chapter 4: Introduction)

aromatic hydrocarbons Hydrocarbon compounds that contain a planar, cyclic arrangement of carbon atoms linked by both σ and delocalized π bonds. (Section 24.2)

Arrhenius equation An equation that relates the rate constant for a reaction to the frequency factor, A, the activation energy, E_a, and the temperature, T: $k = Ae^{-E_a/RT}$. In its logarithmic form it is written $\ln k = -E_a/RT + \ln A$. (Section 14.5)

atmosphere (atm) A unit of pressure equal to 760 torr; $1 \text{ atm} = 101.325 \text{ kPa}$. (Section 10.2)

atom The smallest representative particle of an element. (Sections 1.1 and 2.1)

atomic mass unit (amu) A unit based on the value of exactly 12 amu for the mass of the isotope of carbon that has six protons and six neutrons in the nucleus. (Sections 2.3 and 3.3)

atomic number The number of protons in the nucleus of an atom of an element. (Section 2.3)

atomic radius An estimate of the size of an atom. See bonding atomic radius. (Section 7.3)

atomic weight The average mass of the atoms of an element in atomic mass units (amu); it is numerically equal to the mass in grams of one mole of the element. (Section 2.4)

autoionization The process whereby water spontaneously forms low concentrations of $H^+(aq)$ and $OH^-(aq)$ ions by proton transfer from one water molecule to another. (Section 16.3)

Avogadro's hypothesis A statement that equal volumes of gases at the same temperature and pressure contain equal numbers of molecules. (Section 10.3)

Avogadro's law A statement that the volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas. (Section 10.3)

Avogadro's number (N_A) The number of ^{12}C atoms in exactly 12 g of ^{12}C; it equals $6.022 \times 10^{23} \text{ mol}^{-1}$. (Section 3.4)

band An array of closely spaced molecular orbitals occupying a discrete range of energy. (Section 12.4)

band gap The energy gap between a fully occupied band called a valence band and an empty band called the conduction band. (Section 12.7)

band structure The electronic structure of a solid, defining the allowed ranges of energy for electrons in a solid. (Section 12.7)

bar A unit of pressure equal to 10^5 Pa. (Section 10.2)

base A substance that is an H^+ acceptor; a base produces an excess of $OH^-(aq)$ ions when it dissolves in water. (Section 4.3)

base-dissociation constant (K_b) An equilibrium constant that expresses the extent to which a base reacts with solvent water, accepting a proton and forming $OH^-(aq)$. (Section 16.7)

basic anhydride (basic oxide) An oxide that forms a base when added to water; soluble metal oxides are basic anhydrides. (Section 22.5)

basic oxide (basic anhydride) An oxide that either reacts with water to form a base or reacts with an acid to form a salt and water. (Section 22.5)

battery A self-contained electrochemical power source that contains one or more voltaic cells. (Section 20.7)

becquerel The SI unit of radioactivity. It corresponds to one nuclear disintegration per second. (Section 21.4)

Beer's law The light absorbed by a substance (A) equals the product of its extinction coefficient (ε), the path length through which the light passes (b), and the molar concentration of the substance (c): $A = \varepsilon bc$. (Section 14.2)

beta emission A nuclear decay process where a beta particle is emitted from the nucleus; also called beta decay. (Section 21.1)

beta particles Energetic electrons emitted from the nucleus, symbol ${}_{-1}^{0}e$ or β^-. (Section 21.1)

beta sheet A structural form of protein in which two strands of amino acids are hydrogen-bonded together in a zipperlike configuration. (Section 24.7)

bidentate ligand A ligand in which two linked coordinating atoms are bound to a metal. (Section 23.3)

bimolecular reaction An elementary reaction that involves two molecules. (Section 14.6)

biochemistry The study of the chemistry of living systems. (Chapter 24: Introduction)

biodegradable Organic material that bacteria are able to oxidize. (Section 18.4)

body-centered lattice A crystal lattice in which the lattice points are located at the center and corners of each unit cell. (Section 12.2)

bomb calorimeter A device for measuring the heat evolved in the combustion of a substance under constant-volume conditions. (Section 5.5)

bond angles The angles made by the lines joining the nuclei of the atoms in a molecule. (Section 9.1)

bond dipole The dipole moment that is due to unequal electron sharing between two atoms in a covalent bond. (Section 9.3)

bond enthalpy The enthalpy change, ΔH, required to break a particular bond when the substance is in the gas phase. (Section 8.8)

bonding atomic radius The radius of an atom as defined by the distances separating it from other atoms to which it is chemically bonded. (Section 7.3)

bonding molecular orbital A molecular orbital in which the electron density is concentrated in the internuclear region. The energy of a bonding molecular orbital is lower than the energy of the separate atomic orbitals from which it forms. (Section 9.7)

bonding pair In a Lewis structure a pair of electrons that is shared by two atoms. (Section 9.2)

bond length The distance between the centers of two bonded atoms. (Section 8.3)

bond order The number of bonding electron pairs shared between two atoms, minus the number of antibonding electron pairs: bond order $=$ (number of bonding electrons $-$ number of antibonding electrons)/2. (Section 9.7)

bond polarity A measure of the degree to which the electrons are shared unequally between two atoms in a chemical bond. (Section 8.4)

boranes Covalent hydrides of boron. (Section 22.11)

Born–Haber cycle A thermodynamic cycle based on Hess's law that relates the lattice energy of an ionic substance to its enthalpy of formation and to other measurable quantities. (Section 8.2)

Boyle's law A law stating that at constant temperature, the product of the volume and pressure of a given amount of gas is a constant. (Section 10.3)

Brønsted–Lowry acid A substance (molecule or ion) that acts as a proton donor. (Section 16.2)

Brønsted–Lowry base A substance (molecule or ion) that acts as a proton acceptor. (Section 16.2)

buffer capacity The amount of acid or base a buffer can neutralize before the pH begins to change appreciably. (Section 17.2)

buffered solution (buffer) A solution that undergoes a limited change in pH upon addition of a small amount of acid or base. (Section 17.2)

calcination The heating of an ore to bring about its decomposition and the elimination of a volatile product. For example, a carbonate ore might be calcined to drive off CO_2. (Section 23.2)

calorie A unit of energy; it is the amount of energy needed to raise the temperature of 1 g of water by 1 °C from 14.5 °C to 15.5 °C. A related unit is the joule: 1 cal $=$ 4.184 J. (Section 5.1)

calorimeter An apparatus that measures the heat released or absorbed in a chemical or physical process. (Section 5.5)

calorimetry The experimental measurement of heat produced in chemical and physical processes. (Section 5.5)

capillary action The process by which a liquid rises in a tube because of a combination of adhesion to the walls of the tube and cohesion between liquid particles. (Section 11.3)

carbide A binary compound of carbon with a metal or metalloid. (Section 22.9)

carbohydrates A class of substances formed from polyhydroxy aldehydes or ketones. (Section 24.8)

carbon black A microcrystalline form of carbon. (Section 22.9)

carbonyl group The $C{=}O$ double bond, a characteristic feature of several organic functional groups, such as ketones and aldehydes. (Section 24.4)

carboxylic acid A compound that contains the $-COOH$ functional group. (Sections 16.10 and 24.4)

catalyst A substance that changes the speed of a chemical reaction without itself undergoing a permanent chemical change in the process. (Section 14.7)

cathode An electrode at which reduction occurs. (Section 20.3)

cathode rays Streams of electrons that are produced when a high voltage is applied to electrodes in an evacuated tube. (Section 2.2)

cathodic protection A means of protecting a metal against corrosion by making it the cathode in a voltaic cell. This can be achieved by attaching a more easily oxidized metal, which serves as an anode, to the metal to be protected. (Section 20.8)

cation A positively charged ion. (Section 2.7)

cell potential The potential difference between the cathode and anode in an electrochemical cell; it is measured in volts: $1\ V = 1\ J/C$. Also called electromotive force. (Section 20.4)

cellulose A polysaccharide of glucose; it is the major structural element in plant matter. (Section 24.8)

Celsius scale A temperature scale on which water freezes at 0° and boils at 100° at sea level. (Section 1.4)

chain reaction A series of reactions in which one reaction initiates the next. (Section 21.7)

changes of state Transformations of matter from one state to a different one, for example, from a gas to a liquid. (Section 1.3)

charcoal A form of carbon produced when wood is heated strongly in a deficiency of air. (Section 22.9)

Charles's law A law stating that at constant pressure, the volume of a given quantity of gas is proportional to absolute temperature. (Section 10.3)

chelate effect The generally larger formation constants for polydentate ligands as compared with the corresponding *monodentate* ligands. (Section 23.3)

chelating agent A polydentate ligand that is capable of occupying two or more sites in the coordination sphere. (Section 23.3)

chemical bond A strong attractive force that exists between atoms in a molecule. (Section 8.1)

chemical changes Processes in which one or more substances are converted into other substances; also called chemical reactions. (Section 1.3)

chemical equation A representation of a chemical reaction using the chemical formulas of the reactants and products; a balanced chemical equation contains equal numbers of atoms of each element on both sides of the equation. (Section 3.1)

chemical equilibrium A state of dynamic balance in which the rate of formation of the products of a reaction from the reactants equals the rate of formation of the reactants from the products; at equilibrium the concentrations of the reactants and products remain constant. (Section 4.1; Chapter 15: Introduction)

chemical formula A notation that uses chemical symbols with numerical subscripts to convey the relative proportions of atoms of the different elements in a substance. (Section 2.6)

chemical kinetics The area of chemistry concerned with the speeds, or rates, at which chemical reactions occur. (Chapter 14: Introduction)

chemical nomenclature The rules used in naming substances. (Section 2.8)

chemical properties Properties that describe a substance's composition and its reactivity; how the substance reacts or changes into other substances. (Section 1.3)

chemical reactions Processes in which one or more substances are converted into other substances; also called chemical changes. (Section 1.3)

chemistry The scientific discipline that studies the composition, properties, and transformations of matter. (Chapter 1: Introduction)

chiral A term describing a molecule or an ion that cannot be superimposed on its mirror image. (Sections 23.4 and 24.5)

chlorofluorocarbons Compounds composed entirely of chlorine, fluorine, and carbon. (Section 18.3)

chlorophyll A plant pigment that plays a major role in conversion of solar energy to chemical energy in photosynthesis. (Section 23.3)

cholesteric liquid crystalline phase A liquid crystal formed from flat, disc-shaped molecules that align through a stacking of the molecular discs. (Section 11.7)

coal A naturally occurring solid containing hydrocarbons of high molecular weight, as well as compounds containing sulfur, oxygen, and nitrogen. (Section 5.8)

colligative property A property of a solvent (vapor-pressure lowering, freezing-point lowering, boiling-point elevation, osmotic pressure) that depends on the total concentration of solute particles present. (Section 13.5)

collision model A model of reaction rates based on the idea that molecules must collide to react; it explains the factors influencing reaction rates in terms of the frequency of collisions, the number of collisions with energies exceeding the activation energy, and the probability that the collisions occur with suitable orientations. (Section 14.5)

colloids (colloidal dispersions) Mixtures containing particles larger than normal solutes but small enough to remain suspended in the dispersing medium. (Section 13.6)

combination reaction A chemical reaction in which two or more substances combine to form a single product. (Section 3.2)

combustion reaction A chemical reaction that proceeds with evolution of heat and usually also a flame; most combustion involves reaction with oxygen, as in the burning of a match. (Section 3.2)

common-ion effect A shift of an equilibrium induced by an ion common to the equilibrium. For example, added Na_2SO_4 decreases the solubility of the slightly soluble salt $BaSO_4$, or added NaF decreases the percent ionization of HF. (Section 17.1)

complementary colors Colors that, when mixed in proper proportions, appear white or colorless. (Section 23.5)

complete ionic equation A chemical equation in which dissolved strong electrolytes (such as dissolved ionic compounds) are written as separate ions. (Section 4.2)

complex ion (complex) An assembly of a metal ion and the Lewis bases (ligands) bonded to it. (Section 17.5)

compound A substance composed of two or more elements united chemically in definite proportions. (Section 1.2)

compound semiconductor A semiconducting material formed from two or more elements. (Section 12.7)

concentration The quantity of solute present in a given quantity of solvent or solution. (Section 4.5)

concentration cell A voltaic cell containing the same electrolyte and the same electrode materials in both the anode and cathode compartments. The emf of the cell is derived from a difference in the concentrations of the same electrolyte solutions in the compartments. (Section 20.6)

condensation polymerization Polymerization in which molecules are joined together through condensation reactions. (Section 12.8)

condensation reaction A chemical reaction in which a small molecule (such as a molecule of water) is split out from between two reacting molecules. (Sections 12.6 and 22.8)

conduction band A band of molecular orbitals lying higher in energy than the occupied valence band and distinctly separated from it. (Section 12.7)

conjugate acid A substance formed by addition of a proton to a Brønsted–Lowry base. (Section 16.2)

conjugate acid–base pair An acid and a base, such as H_2O and OH^-, that differ only in the presence or absence of a proton. (Section 16.2)

conjugate base A substance formed by the loss of a proton from a Brønsted–Lowry acid. (Section 16.2)

continuous spectrum A spectrum that contains radiation distributed over all wavelengths. (Section 6.3)

conversion factor A ratio relating the same quantity in two systems of units that is used to convert the units of measurement. (Section 1.6)

coordination compound A compound containing a metal ion bonded to a group of surrounding molecules or ions that act as ligands. (Section 23.2)

coordination number The number of adjacent atoms to which an atom is directly bonded. In a complex the coordination number of the metal ion is the number of donor atoms to which it is bonded. (Sections 12.37 and 24.2)

coordination sphere The metal ion and its surrounding ligands. (Section 23.2)

coordination-sphere isomers Structural isomers of coordination compounds in which the ligands within the coordination sphere differ. (Section 23.4)

copolymer A complex polymer resulting from the polymerization of two or more chemically different monomers. (Section 12.8)

core electrons The electrons that are not in the outermost shell of an atom. (Section 6.8)

corrosion The process by which a metal is oxidized by substances in its environment. (Section 20.8)

covalent bond A bond formed between two or more atoms by a sharing of electrons. (Section 8.1)

covalent-network solids Solids in which the units that make up the three-dimensional network are joined by covalent bonds. (Section 12.1)

critical mass The amount of fissionable material necessary to maintain a nuclear chain reaction. (Section 21.7)

critical pressure The pressure at which a gas at its critical temperature is converted to a liquid state. (Section 11.4)

critical temperature The highest temperature at which it is possible to convert the gaseous form of a substance to a liquid. The critical temperature increases with an increase in the magnitude of intermolecular forces. (Section 11.4)

crystal-field theory A theory that accounts for the colors and the magnetic and other properties of transition-metal complexes in terms of the splitting of the energies of metal ion d orbitals by the electrostatic interaction with the ligands. (Section 23.6)

crystal lattice An imaginary network of points on which the repeating motif of a solid may be imagined to be laid down so that the structure of the crystal is obtained. The motif may be a single atom or a group of atoms. Each lattice point represents an identical environment in the crystal. (Section 12.2)

crystalline solid (crystal) A solid whose internal arrangement of atoms, molecules, or ions possesses a regularly repeating pattern in any direction through the solid. (Section 12.2)

crystallization The process in which molecules, ions, or atoms come together to form a crystalline solid. (Section 13.2)

cubic close packing A crystal structure where the atoms are packed together as close as possible, and the close-packed layers of atoms adopt a three-layer repeating pattern that leads to a face-centered cubic unit cell. (Section 12.3)

curie A measure of radioactivity: 1 curie $=$ 3.7×10^{10} nuclear disintegrations per second. (Section 21.4)

cycloalkanes Saturated hydrocarbons of general formula C_nH_{2n} in which the carbon atoms form a closed ring. (Section 24.2)

Dalton's law of partial pressures A law stating that the total pressure of a mixture of gases is the sum of the pressures that each gas would exert if it were present alone. (Section 10.6)

***d–d* transition** The transition of an electron in a transition-metal compound from a lower-energy *d* orbital to a higher-energy *d* orbital. (Section 23.6)

decomposition reaction A chemical reaction in which a single compound reacts to give two or more products. (Section 3.2)

degenerate A situation in which two or more orbitals have the same energy. (Section 6.7)

delocalized electrons Electrons that are spread over a number of atoms in a molecule or a crystal rather than localized on a single atom or a pair of atoms. (Section 9.6)

density The ratio of an object's mass to its volume. (Section 1.4)

deoxyribonucleic acid (DNA) A polynucleotide in which the sugar component is deoxyribose. (Section 24.10)

desalination The removal of salts from seawater, brine, or brackish water to make it fit for human consumption. (Section 18.4)

deuterium The isotope of hydrogen whose nucleus contains a proton and a neutron: $^{2}_{1}H$. (Section 22.2)

dextrorotatory, or merely dextro or *d* A term used to label a chiral molecule that rotates the plane of polarization of plane-polarized light to the right (clockwise). (Section 23.4)

diamagnetism A type of magnetism that causes a substance with no unpaired electrons to be weakly repelled from a magnetic field. (Section 9.8)

diatomic molecule A molecule composed of only two atoms. (Section 2.6)

diffusion The spreading of one substance through a space occupied by one or more other substances. (Section 10.8)

dilution The process of preparing a less concentrated solution from a more concentrated one by adding solvent. (Section 4.5)

dimensional analysis A method of problem solving in which units are carried through all calculations. Dimensional analysis ensures that the final answer of a calculation has the desired units. (Section 1.6)

dipole A molecule with one end having a partial negative charge and the other end having a partial positive charge; a polar molecule. (Section 8.4)

dipole–dipole force A force that becomes significant when polar molecules come in close contact with one another. The force is attractive when the positive end of one polar molecule approaches the negative end of another. (Section 11.2)

dipole moment A measure of the separation and magnitude of the positive and negative charges in polar molecules. (Section 8.4)

dispersion forces Intermolecular forces resulting from attractions between induced dipoles. Also called London dispersion forces. (Section 11.2)

displacement reaction A reaction in which an element reacts with a compound, displacing an element from it. (Section 4.4)

donor atom The atom of a ligand that bonds to the metal. (Section 23.2)

doping Incorporation of a hetero atom into a solid to change its electrical properties. For example, incorporation of P into Si. (Section 12.7)

double bond A covalent bond involving two electron pairs. (Section 8.3)

double helix The structure for DNA that involves the winding of two DNA polynucleotide chains together in a helical arrangement. The two strands of the double helix are complementary in that the organic bases on the two strands are paired for optimal hydrogen bond interaction. (Section 24.10)

dynamic equilibrium A state of balance in which opposing processes occur at the same rate. (Section 11.5)

effective nuclear charge The net positive charge experienced by an electron in a many-electron atom; this charge is not the full nuclear charge because there is some shielding of the nucleus by the other electrons in the atom. (Section 7.2)

effusion The escape of a gas through an orifice or hole. (Section 10.8)

elastomer A material that can undergo a substantial change in shape via stretching, bending, or compression and return to its original shape upon release of the distorting force. (Section 12.6)

electrochemistry The branch of chemistry that deals with the relationships between electricity and chemical reactions. (Chapter 20: Introduction)

electrolysis reaction A reaction in which a nonspontaneous redox reaction is brought about by the passage of current under a sufficient external electrical potential. The devices in which electrolysis reactions occur are called electrolytic cells. (Section 20.9)

electrolyte A solute that produces ions in solution; an electrolytic solution conducts an electric current. (Section 4.1)

electrolytic cell A device in which a nonspontaneous oxidation–reduction reaction is caused to occur by passage of current under a sufficient external electrical potential. (Section 20.9)

electromagnetic radiation (radiant energy) A form of energy that has wave characteristics and that propagates through a vacuum at the characteristic speed of 3.00×10^{8} m/s. (Section 6.1)

electrometallurgy The use of electrolysis to reduce or refine metals. (Section 20.9)

electromotive force (emf) A measure of the driving force, or *electrical pressure*, for the completion of an electrochemical reaction. Electromotive force is measured in volts: $1\ V = 1\ J/C$. Also called the cell potential. (Section 20.4)

electron A negatively charged subatomic particle found outside the atomic nucleus; it is a part of all atoms. An electron has a mass 1/1836 times that of a proton. (Section 2.3)

electron affinity The energy change that occurs when an electron is added to a gaseous atom or ion. (Section 7.5)

electron capture A mode of radioactive decay in which an inner-shell orbital electron is captured by the nucleus. (Section 21.1)

electron configuration The arrangement of electrons in the orbitals of an atom or molecule (Section 6.8)

electron density The probability of finding an electron at any particular point in an atom; this probability is equal to ψ^2, the square of the wave function. Also called the probability density. (Section 6.5)

electron domain In the VSEPR model, a region about a central atom in which an electron pair is concentrated. (Section 9.2)

electron-domain geometry The three-dimensional arrangement of the electron domains around an atom according to the VSEPR model. (Section 9.2)

electronegativity A measure of the ability of an atom that is bonded to another atom to attract electrons to itself. (Section 8.4)

electronic charge The negative charge carried by an electron; it has a magnitude of 1.602×10^{-19} C. (Section 2.3)

electronic structure The arrangement of electrons in an atom or molecule. (Chapter 6: Introduction)

electron-sea model A model for the behavior of electrons in metals. (Section 12.4)

electron shell A collection of orbitals that have the same value of *n*. For example, the orbitals with $n = 3$ (the 3*s*, 3*p*, and 3*d* orbitals) comprise the third shell. (Section 6.5)

electron spin A property of the electron that makes it behave as though it were a tiny magnet. The electron behaves as if it were spinning on its axis; electron spin is quantized. (Section 6.7)

element A substance consisting of atoms of the same atomic number. Historically defined as a substance that cannot be separated into simpler substances by chemical means. (Sections 1.1 and 1.2)

elemental semiconductor A semiconducting material composed of just one element. (Section 12.7)

elementary reaction A process in a chemical reaction that occurs in a single step. An overall chemical reaction consists of one or more elementary reactions or steps. (Section 14.6)

empirical formula A chemical formula that shows the kinds of atoms and their relative numbers in a substance in the smallest possible whole-number ratios. (Section 2.6)

enantiomers Two mirror-image molecules of a chiral substance. The enantiomers are nonsuperimposable. (Section 23.4)

endothermic process A process in which a system absorbs heat from its surroundings. (Section 5.2)

energy The capacity to do work or to transfer heat. (Section 5.1)

energy-level diagram A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived. Also called a **molecular-orbital diagram**. (Section 9.7)

enthalpy A quantity defined by the relationship $H = E + PV$; the enthalpy change, ΔH, for a reaction that occurs at constant pressure is the heat evolved or absorbed in the reaction: $\Delta H = q_p$. (Section 5.3)

enthalpy of formation The enthalpy change that accompanies the formation of a substance from the most stable forms of its component elements. (Section 5.7)

enthalpy of reaction The enthalpy change associated with a chemical reaction. (Section 5.4)

entropy A thermodynamic function associated with the number of different equivalent energy states or spatial arrangements in which a system may be found. It is a thermodynamic state function, which means that once we specify the conditions for a system—that is, the temperature, pressure, and so on—the entropy is defined. (Section 19.2)

enzyme A protein molecule that acts to catalyze specific biochemical reactions. (Section 14.7)

equilibrium constant The numerical value of the equilibrium-constant expression for a system at equilibrium. The equilibrium constant is most usually denoted by K_p for gas-phase systems or K_c for solution-phase systems. (Section 15.2)

equilibrium-constant expression The expression that describes the relationship among the concentrations (or partial pressures) of the substances present in a system at equilibrium. The numerator is obtained by multiplying the concentrations of the substances on the product side of the equation, each raised to a power equal to its coefficient in the chemical equation. The denominator similarly contains the concentrations of the substances on the reactant side of the equation. (Section 15.2)

equivalence point The point in a titration at which the added solute reacts completely with the solute present in the solution. (Section 4.6)

ester An organic compound that has an OR group attached to a carbonyl; it is the product of a reaction between a carboxylic acid and an alcohol. (Section 24.4)

ether A compound in which two hydrocarbon groups are bonded to one oxygen. (Section 24.4)

exchange (metathesis) reaction A reaction between compounds that when written as a molecular equation appears to involve the exchange of ions between the two reactants. (Section 4.2)

excited state A higher energy state than the ground state. (Section 6.3)

exothermic process A process in which a system releases heat to its surroundings. (Section 5.2)

extensive property A property that depends on the amount of material considered; for example, mass or volume. (Section 1.3)

face-centered lattice A crystal lattice in which the lattice points are located at the faces and corners of each unit cell. (Section 12.2)

Faraday constant (*F*) The magnitude of charge of one mole of electrons: 96,500 C/mol. (Section 20.5)

***f*-block metals** Lanthanide and actinide elements in which the 4*f* or 5*f* orbitals are partially occupied. (Section 6.9)

ferrimagnetism A form of magnetism in which unpaired electron spins on different-type ions point in opposite directions but do not fully cancel out. (Section 23.1)

ferromagnetism A form of magnetism in which unpaired electron spins align parallel to one another. (Section 23.1)

first law of thermodynamics A statement that energy is conserved in any process. One way to express the law is that the change in internal energy, ΔE, of a system in any process is equal to the heat, q, added to the system, plus the work, w, done on the system by its surroundings: $\Delta E = q + w$. (Section 5.2)

first-order reaction A reaction in which the reaction rate is proportional to the concentration of a single reactant, raised to the first power. (Section 14.4)

fission The splitting of a large nucleus into two smaller ones. (Section 21.6)

folding The process by which a protein adopts its biologically active shape. (Section 24.7)

force A push or a pull. (Section 5.1)

formal charge The number of valence electrons in an isolated atom minus the number of electrons assigned to the atom in the Lewis structure. (Section 8.5)

formation constant For a metal ion complex, the equilibrium constant for formation of the complex from the metal ion and base species present in solution. It is a measure of the tendency of the complex to form. (Section 17.5)

formula weight The mass of the collection of atoms represented by a chemical formula. For example, the formula weight of NO_2 (46.0 amu) is the sum of the masses of one nitrogen atom and two oxygen atoms. (Section 3.3)

fossil fuels Coal, oil, and natural gas, which are presently our major sources of energy. (Section 5.8)

fracking The practice in which water laden with sand and other materials is pumped at high pressure into rock formations to release natural gas and other petroleum materials. (Section 18.4)

free energy (Gibbs free energy, *G*) A thermodynamic state function that gives a criterion for spontaneous change in terms of enthalpy and entropy: $G = H - TS$. (Section 19.5)

free radical A substance with one or more unpaired electrons. (Section 21.9)

frequency The number of times per second that one complete wavelength passes a given point. (Section 6.1)

frequency factor (*A*) A term in the Arrhenius equation that is related to the frequency of collision and the probability that the collisions are favorably oriented for reaction. (Section 14.5)

fuel cell A voltaic cell that utilizes the oxidation of a conventional fuel, such as H_2 or CH_4, in the cell reaction. (Section 20.7)

fuel value The energy released when 1 g of a substance is combusted. (Section 5.8)

functional group An atom or group of atoms that imparts characteristic chemical properties to an organic compound. (Section 24.1)

fusion The joining of two light nuclei to form a more massive one. (Section 21.6)

galvanic cell See **voltaic cell**. (Section 20.3)

gamma radiation Energetic electromagnetic radiation emanating from the nucleus of a radioactive atom. (Section 21.1)

gas Matter that has no fixed volume or shape; it conforms to the volume and shape of its container. (Section 1.2)

gas constant (*R*) The constant of proportionality in the ideal-gas equation. (Section 10.4)

geometric isomerism A form of isomerism in which compounds with the same type and number of atoms and the same chemical bonds have different spatial arrangements of these atoms and bonds. (Sections 23.4 and 24.4)

Gibbs free energy A thermodynamic state function that combines enthalpy and entropy, in the form $G = H - TS$. For a change occurring at constant temperature and pressure, the change in free energy is $\Delta G = \Delta H - T\Delta S$. (Section 19.5)

glass An amorphous solid formed by fusion of SiO_2, CaO, and Na_2O. Other oxides may also be used to form glasses with differing characteristics. (Section 22.10)

glucose A polyhydroxy aldehyde whose formula is $CH_2OH(CHOH)_4CHO$; it is the most important of the monosaccharides. (Section 24.8)

glycogen The general name given to a group of polysaccharides of glucose that are synthesized in mammals and used to store energy from carbohydrates. (Section 24.7)

Graham's law A law stating that the rate of effusion of a gas is inversely proportional to the square root of its molecular weight. (Section 10.8)

gray (Gy) The SI unit for radiation dose corresponding to the absorption of 1 J of energy per kilogram of biological material; 1 Gy = 100 rads. (Section 21.9)

green chemistry Chemistry that promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. (Section 18.5)

greenhouse gases Gases in an atmosphere that absorb and emit infrared radiation (radiant heat), "trapping" heat in the atmosphere. (Section 18.2)

ground state The lowest-energy, or most stable, state. (Section 6.3)

group Elements that are in the same column of the periodic table; elements within the same group or family exhibit similarities in their chemical behavior. (Section 2.5)

Haber process The catalyst system and conditions of temperature and pressure developed by Fritz Haber and coworkers for the formation of NH_3 from H_2 and N_2. (Section 15.2)

half-life The time required for the concentration of a reactant substance to decrease to half its initial value; the time required for half of a sample of a particular radioisotope to decay. (Sections 14.4 and 21.4)

half-reaction An equation for either an oxidation or a reduction that explicitly shows the electrons involved, for example, $Zn^{2+}(aq) + 2\,e^- \longrightarrow Zn(s)$. (Section 20.2)

halogens Members of group 7A in the periodic table. (Section 7.8)

hard water Water that contains appreciable concentrations of Ca^{2+} and Mg^{2+}; these ions react with soaps to form an insoluble material. (Section 18.4)

heat The flow of energy from a body at higher temperature to one at lower temperature when they are placed in thermal contact. (Section 5.1)

heat capacity The quantity of heat required to raise the temperature of a sample of matter by 1 °C (or 1 K). (Section 5.5)

heat of fusion The enthalpy change, ΔH, for melting a solid. (Section 11.4)

heat of sublimation The enthalpy change, ΔH, for vaporization of a solid. (Section 11.4)

heat of vaporization The enthalpy change, ΔH, for vaporization of a liquid. (Section 11.4)

Henderson–Hasselbalch equation The relationship among the pH, pK_a, and the concentrations of acid and conjugate base in an aqueous solution: $\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$. (Section 17.2)

Henry's law A law stating that the concentration of a gas in a solution, Sg, is proportional to the pressure of gas over the solution: $S_g = kP_g$. (Section 13.3)

Hess's law The heat evolved in a given process can be expressed as the sum of the heats of several processes that, when added, yield the process of interest. (Section 5.6)

heterogeneous alloy An alloy in which the components are not distributed uniformly; instead, two or more distinct phases with characteristic compositions are present. (Section 12.3)

heterogeneous catalyst A catalyst that is in a different phase from that of the reactant substances. (Section 14.7)

heterogeneous equilibrium The equilibrium established between substances in two or more different phases, for example, between a gas and a solid or between a solid and a liquid. (Section 15.4)

hexagonal close packing A crystal structure where the atoms are packed together as closely as possible. The close-packed layers adopt a two-layer repeating pattern, which leads to a primitive hexagonal unit cell. (Section 12.3)

high-spin complex A complex whose electrons populate the d orbitals to give the maximum number of unpaired electrons. (Section 23.6)

hole A vacancy in the valence band of a semiconductor, created by doping. (Section 12.7)

homogeneous catalyst A catalyst that is in the same phase as the reactant substances. (Section 14.7)

homogeneous equilibrium The equilibrium established between reactant and product substances that are all in the same phase. (Section 15.4)

Hund's rule A rule stating that electrons occupy degenerate orbitals in such a way as to maximize the number of electrons with the same spin. In other words, each orbital has one electron placed in it before pairing of electrons in orbitals occurs. (Section 6.8)

hybridization The mixing of different types of atomic orbitals to produce a set of equivalent hybrid orbitals. (Section 9.5)

hybrid orbital An orbital that results from the mixing of different kinds of atomic orbitals on the same atom. For example, an sp^3 hybrid results from the mixing, or hybridizing, of one s orbital and three *p* orbitals. (Section 9.5)

hydration Solvation when the solvent is water. (Section 13.1)

hydride ion An ion formed by the addition of an electron to a hydrogen atom: H^-. (Section 7.7)

hydrocarbons Compounds composed of only carbon and hydrogen. (Section 2.9)

hydrogen bonding Bonding that results from intermolecular attractions between molecules containing hydrogen bonded to an electronegative element. The most important examples involve OH, NH, and HF. (Section 11.2)

hydrolysis A reaction with water. When a cation or anion reacts with water, it changes the pH. (Sections 16.9 and 24.4)

hydronium ion (H_3O^+) The predominant form of the proton in aqueous solution. (Section 16.2)

hydrophilic Water attracting. The term is often used to describe a type of colloid. (Section 13.6)

hydrophobic Water repelling. The term is often used to describe a type of colloid. (Section 13.6)

hypothesis A tentative explanation of a series of observations or of a natural law. (Section 1.3)

ideal gas A hypothetical gas whose pressure, volume, and temperature behavior is completely described by the ideal-gas equation. (Section 10.4)

ideal-gas equation An equation of state for gases that embodies Boyle's law, Charles's law, and Avogadro's hypothesis in the form $PV = nRT$. (Section 10.4)

ideal solution A solution that obeys Raoult's law. (Section 13.5)

immiscible liquids Liquids that do not dissolve in one another to a significant extent. (Section 13.3)

indicator A substance added to a solution that changes color when the added solute has reacted with all the solute present in solution. The most common type of indicator is an acid–base indicator whose color changes as a function of pH. (Section 4.6)

instantaneous rate The reaction rate at a particular time as opposed to the average rate over an interval of time. (Section 14.2)

insulators Materials that do not conduct electricity. (Section 12.7)

intensive property A property that is independent of the amount of material considered, for example, density. (Section 1.3)

interhalogens Compounds formed between two different halogen elements. Examples include IBr and BrF_3. (Section 22.4)

intermediate A substance formed in one elementary step of a multistep mechanism and consumed in another; it is neither a reactant nor an ultimate product of the overall reaction. (Section 14.6)

intermetallic compound A homogeneous alloy with definite properties and a fixed composition. Intermetallic compounds are stoichiometric compounds that form between metallic elements. (Section 12.3)

intermolecular forces The short-range attractive forces operating between the particles that make up the units of a liquid or solid substance. These same forces also cause gases to liquefy or solidify at low temperatures and high pressures. (Chapter 11: Introduction)

internal energy The total energy possessed by a system. When a system undergoes a change, the change in internal energy, ΔE, is defined as the heat, q, added to the system, plus the work, w, done on the system by its surroundings: $\Delta E = q + w$. (Section 5.2)

interstitial alloy An alloy in which smaller atoms fit into spaces between larger atoms. The larger atoms are metallic elements and the smaller atoms are typically nonmetallic elements. (Section 12.3)

ion Electrically charged atom or group of atoms (polyatomic ion); ions can be positively or negatively charged, depending on whether electrons are lost (positive) or gained (negative) by the atoms. (Section 2.7)

ion–dipole force The force that exists between an ion and a neutral polar molecule that possesses a permanent dipole moment. (Section 11.2)

ionic bond A bond between oppositely charged ions. The ions are formed from atoms by transfer of one or more electrons. (Section 8.1)

ionic compound A compound composed of cations and anions. (Section 2.7)

ionic hydrides Compounds formed when hydrogen reacts with alkali metals and also the heavier alkaline earths (Ca, Sr, and Ba); these compounds contain the hydride ion, H^-. (Section 22.2)

ionic solids Solids that are composed of ions. (Section 12.1)

ionization energy The energy required to remove an electron from a gaseous atom when the atom is in its ground state. (Section 7.4)

ionizing radiation Radiation that has sufficient energy to remove an electron from a molecule, thereby ionizing it. (Section 21.9)

ion-product constant For water, K_w is the product of the aquated hydrogen ion and hydroxide ion concentrations: $[\mathrm{H}^+][\mathrm{OH}^-] = K_\mathrm{w} = 1.0 \times 10^{-14}$ at 25 °C. (Section 16.3)

irreversible process A process that cannot be reversed to restore both the system and its surroundings to their original states. Any spontaneous process is irreversible. (Section 19.1)

isoelectronic series A series of atoms, ions, or molecules having the same number of electrons. (Section 7.3)

isomers Compounds whose molecules have the same overall composition but different structures. (Sections 2.9 and 23.4)

isothermal process One that occurs at constant temperature. (Section 19.1)

isotopes Atoms of the same element containing different numbers of neutrons and therefore having different masses. (Section 2.3)

joule (J) The SI unit of energy, $1\ \mathrm{kg\text{-}m^2/s^2}$. A related unit is the calorie: $4.184\ \mathrm{J} = 1\ \mathrm{cal}$. (Section 5.1)

Kelvin scale The absolute temperature scale; the SI unit for temperature is the kelvin. Zero on the Kelvin scale corresponds to −273.15 °C. (Section 1.4)

ketone A compound in which the carbonyl group $(\mathrm{C{=}O})$ occurs at the interior of a carbon chain and is therefore flanked by carbon atoms. (Section 24.4)

kinetic energy The energy that an object possesses by virtue of its motion. (Section 5.1)

kinetic-molecular theory A set of assumptions about the nature of gases. These assumptions, when translated into mathematical form, yield the ideal-gas equation. (Section 10.7)

lanthanide contraction The gradual decrease in atomic and ionic radii with increasing atomic number among the lanthanide elements, atomic numbers 57 through 70. The decrease arises because of a gradual increase in effective nuclear charge through the lanthanide series. (Section 23.1)

lanthanide (rare earth) element Element in which the 4*f* subshell is only partially occupied. (Sections 6.8 and 6.9)

lattice energy The energy required to separate completely the ions in an ionic solid. (Section 8.2)

lattice points Points in a crystal all of which have identical environments. (Section 12.2)

lattice vectors The vectors ***a***, ***b***, and ***c*** that define a crystal lattice. The position of any lattice point in a crystal can be represented by summing integer multiples of the lattice vectors. (Section 12.2)

law of constant composition A law that states that the elemental composition of a pure compound is always the same, regardless of its source; also called the **law of definite proportions**. (Section 1.2)

law of definite proportions A law that states that the elemental composition of a pure substance is always the same, regardless of its source; also called the **law of constant composition**. (Section 1.2)

law of mass action The rules by which the equilibrium constant is expressed in terms of the concentrations of reactants and products, in accordance with the balanced chemical equation for the reaction. (Section 15.2)

Le Châtelier's principle A principle stating that when we disturb a system at chemical equilibrium, the relative concentrations of reactants and products shift so as to partially undo the effects of the disturbance. (Section 15.7)

levorotatory, or merely levo or *l* A term used to label a chiral molecule that rotates the plane of polarization of plane-polarized light to the left (counterclockwise). (Section 24.4)

Lewis base An electron-pair donor. (Section 16.11)

Lewis structure A representation of covalent bonding in a molecule that is drawn using Lewis symbols. Shared electron pairs are shown as lines, and unshared electron pairs are shown as pairs of dots. Only the valence-shell electrons are shown. (Section 8.3)

Lewis symbol (electron-dot symbol) The chemical symbol for an element, with a dot for each valence electron. (Section 8.1)

ligand An ion or molecule that coordinates to a metal atom or to a metal ion to form a complex. (Section 23.2)

limiting reactant (limiting reagent) The reactant present in the smallest stoichiometric quantity in a mixture of reactants; the amount of product that can form is limited by the complete consumption of the limiting reactant. (Section 3.7)

line spectrum A spectrum that contains radiation at only certain specific wavelengths. (Section 6.3)

linkage isomers Structural isomers of coordination compounds in which a ligand differs in its mode of attachment to a metal ion. (Section 23.4)

lipid A nonpolar molecule derived from glycerol and fatty acids that is used by organisms for long-term energy storage. (Section 24.9)

liquid Matter that has a distinct volume but no specific shape. (Section 1.2)

liquid crystal A substance that exhibits one or more partially ordered liquid phases above the melting point of the solid form. By contrast, in nonliquid crystalline substances the liquid phase that forms upon melting is completely unordered. (Section 11.7)

lock-and-key model A model of enzyme action in which the substrate molecule is pictured as fitting rather specifically into the active site on the enzyme. It is assumed that in being bound to the active site, the substrate is somehow activated for reaction. (Section 14.7)

low-spin complex A metal complex in which the electrons are paired in lower-energy orbitals. (Section 23.6)

magic numbers Numbers of protons and neutrons that result in very stable nuclei. (Section 21.2)

main-group elements Elements in the *s* and *p* blocks of the periodic table. (Section 6.9)

mass A measure of the amount of material in an object. It measures the resistance of an object to being moved. In SI units, mass is measured in kilograms. (Section 1.4)

mass defect The difference between the mass of a nucleus and the total masses of the individual nucleons that it contains. (Section 21.6)

mass number The sum of the number of protons and neutrons in the nucleus of a particular atom. (Section 2.3)

mass percentage The number of grams of solute in each 100 g of solution. (Section 13.4)

mass spectrometer An instrument used to measure the precise masses and relative amounts of atomic and molecular ions. (Section 2.4)

matter Anything that occupies space and has mass; the physical material of the universe. (Section 1.1)

matter waves The term used to describe the wave characteristics of a moving particle. (Section 6.4)

mean free path The average distance traveled by a gas molecule between collisions. (Section 10.8)

metal complex An assembly of a metal ion and the Lewis bases bonded to it. (Section 23.2)

metallic bond Bonding, usually in solid metals, in which the bonding electrons are relatively free to move throughout the three-dimensional structure. (Section 8.1)

metallic character The extent to which an element exhibits the physical and chemical properties characteristic of metals, for example, luster, malleability, ductility, and good thermal and electrical conductivity. (Section 7.6)

metallic elements (metals) Elements that are usually solids at room temperature, exhibit high electrical and heat conductivity, and appear lustrous. Most of the elements in the periodic table are metals. (Sections 2.5 and 12.1)

metallic hydrides Compounds formed when hydrogen reacts with transition metals; these compounds contain the hydride ion, H^-. (Section 22.2)

metallic solids Solids that are composed of metal atoms. (Section 12.1)

metalloids Elements that lie along the diagonal line separating the metals from the nonmetals in the periodic table; the properties of metalloids are intermediate between those of metals and nonmetals. (Section 2.5)

metallurgy The science of extracting metals from their natural sources by a combination of chemical and physical processes. It is also concerned with the properties and structures of metals and alloys. (Section 23.1)

metathesis (exchange) reaction A reaction in which two substances react through an exchange of their component ions: $AX + BY \longrightarrow AY + BX$. Precipitation and acid–base neutralization reactions are examples of metathesis reactions. (Section 4.2)

metric system A system of measurement used in science and in most countries. The meter and the gram are examples of metric units. (Section 1.4)

microstate The state of a system at a particular instant; one of many possible energetically equivalent ways to arrange the components of a system to achieve a particular state. (Section 19.3)

mineral A solid, inorganic substance occurring in nature, such as calcium carbonate, which occurs as calcite. (Section 23.1)

miscible liquids Liquids that mix in all proportions. (Section 13.3)

mixture A combination of two or more substances in which each substance retains its own chemical identity. (Section 1.2)

molal boiling-point-elevation constant (K_b) A constant characteristic of a particular solvent that gives the increase in boiling point as a function of solution molality: $\Delta T_b = K_b m$. (Section 13.5)

molal freezing-point-depression constant (K_f) A constant characteristic of a particular solvent that gives the decrease in freezing point as a function of solution molality: $\Delta T_f = -K_f m$. (Section 13.5)

molality The concentration of a solution expressed as moles of solute per kilogram of solvent; abbreviated *m*. (Section 13.4)

molar heat capacity The heat required to raise the temperature of one mole of a substance by 1 °C. (Section 5.5)

molarity The concentration of a solution expressed as moles of solute per liter of solution; abbreviated *M*. (Section 4.5)

molar mass The mass of one mole of a substance in grams; it is numerically equal to the formula weight in atomic mass units. (Section 3.4)

mole A collection of Avogadro's number (6.022×10^{23}) of objects; for example, a mole of H_2O is 6.022×10^{23} H_2O molecules. (Section 3.4)

molecular compound A compound that consists of molecules. (Section 2.6)

molecular equation A chemical equation in which the formula for each substance is written without regard for whether it is an electrolyte or a nonelectrolyte. (Section 4.2)

molecular formula A chemical formula that indicates the actual number of atoms of each element in one molecule of a substance. (Section 2.6)

molecular geometry The arrangement in space of the atoms of a molecule. (Section 9.2)

molecular hydrides Compounds formed when hydrogen reacts with nonmetals and metalloids. (Section 22.2)

molecularity The number of molecules that participate as reactants in an elementary reaction. (Section 14.6)

molecular orbital (MO) An allowed state for an electron in a molecule. According to molecular-orbital theory, a molecular orbital is entirely analogous to an atomic orbital, which is an allowed state for an electron in an atom. Most bonding molecular orbitals can be classified as σ or π, depending on the disposition of electron density with respect to the internuclear axis. (Section 9.7)

molecular-orbital diagram A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived; also called an **energy-level diagram**. (Section 9.7)

molecular-orbital theory A theory that accounts for the allowed states for electrons in molecules. (Section 9.7)

molecular solids Solids that are composed of molecules. (Sections 12.1 and 12.6)

molecular weight The mass of the collection of atoms represented by the chemical formula for a molecule. (Section 3.3)

molecule A chemical combination of two or more atoms. (Sections 1.1 and 2.6)

mole fraction The ratio of the number of moles of one component of a mixture to the total moles of all components; abbreviated *X*, with a subscript to identify the component. (Section 10.6)

momentum The product of the mass, *m*, and velocity, *v*, of an object. (Section 6.4)

monodentate ligand A ligand that binds to the metal ion via a single donor atom. It occupies one position in the coordination sphere. (Section 23.3)

monomers Molecules with low molecular weights, which can be joined together (polymerized) to form a polymer. (Section 12.8)

monosaccharide A simple sugar, most commonly containing six carbon atoms. The joining together of monosaccharide units by condensation reactions results in formation of polysaccharides. (Section 24.8)

nanomaterial A solid whose dimensions range from 1 to 100 nm and whose properties differ from those of a bulk material with the same composition. (Section 12.1)

natural gas A naturally occurring mixture of gaseous hydrocarbon compounds composed of hydrogen and carbon. (Section 5.8)

nematic liquid crystalline phase A liquid crystal in which the molecules are aligned in the same general direction, along their long axes, but in which the ends of the molecules are not aligned. (Section 11.7)

Nernst equation An equation that relates the cell emf, *E*, to the standard emf, $E°$, and the reaction quotient, Q: $E = E° - (RT/nF) \ln Q$. (Section 20.6)

net ionic equation A chemical equation for a solution reaction in which soluble strong electrolytes are written as ions and spectator ions are omitted. (Section 4.2)

neutralization reaction A reaction in which an acid and a base react in stoichiometrically equivalent amounts; the neutralization reaction between an acid and a metal hydroxide produces water and a salt. (Section 4.3)

neutron An electrically neutral particle found in the nucleus of an atom; it has approximately the same mass as a proton. (Section 2.3)

noble gases Members of group 8A in the periodic table. (Section 7.8)

node Points in an atom at which the electron density is zero. For example, the node in a 2s orbital is a spherical surface. (Section 6.6)

nonbonding pair In a Lewis structure a pair of electrons assigned completely to one atom; also called a lone pair. (Section 9.2)

nonelectrolyte A substance that does not ionize in water and consequently gives a nonconducting solution. (Section 4.1)

nonionizing radiation Radiation that does not have sufficient energy to remove an electron from a molecule. (Section 21.9)

nonmetallic elements (nonmetals) Elements in the upper right corner of the periodic table; nonmetals differ from metals in their physical and chemical properties. (Section 2.5)

nonpolar covalent bond A covalent bond in which the electrons are shared equally. (Section 8.4)

normal boiling point The boiling point at 1 atm pressure. (Section 11.5)

normal melting point The melting point at 1 atm pressure. (Section 11.6)

nuclear binding energy The energy required to decompose an atomic nucleus into its component protons and neutrons. (Section 21.6)

nuclear disintegration series A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one; also called a radioactive series. (Section 21.2)

nuclear model Model of the atom with a nucleus containing protons and neutrons and with electrons in the space outside the nucleus. (Section 2.2)

nuclear transmutation A conversion of one kind of nucleus to another. (Section 21.3)

nucleic acids Polymers of high molecular weight that carry genetic information and control protein synthesis. (Section 24.10)

nucleon A particle found in the nucleus of an atom. (Section 21.1)

nucleotide Compounds formed from a molecule of phosphoric acid, a sugar molecule, and an organic nitrogen base. Nucleotides form linear polymers called DNA and RNA, which are involved in protein synthesis and cell reproduction. (Section 24.10)

nucleus The very small, very dense, positively charged portion of an atom; it is composed of protons and neutrons. (Section 2.2)

octet rule A rule stating that bonded atoms tend to possess or share a total of eight valence-shell electrons. (Section 8.1)

optical isomerism A form of isomerism in which the two forms of a compound (stereoisomers) are nonsuperimposable mirror images. (Section 23.4)

optically active Possessing the ability to rotate the plane of polarized light. (Section 23.4)

orbital An allowed energy state of an electron in the quantum mechanical model of the atom; the term *orbital* is also used to describe the spatial distribution of the electron. An orbital is defined by the values of three quantum numbers: n, l, and m_l (Section 6.5)

organic chemistry The study of carbon-containing compounds, typically containing carbon–carbon bonds. (Section 2.9; Chapter 24: Introduction)

osmosis The net movement of solvent through a semipermeable membrane toward the solution with greater solute concentration. (Section 13.5)

osmotic pressure The pressure that must be applied to a solution to stop osmosis from pure solvent into the solution. (Section 13.5)

Ostwald process An industrial process used to make nitric acid from ammonia. The NH_3 is catalytically oxidized by O_2 to form NO; NO in air is oxidized to NO_2; HNO_3 is formed in a disproportionation reaction when NO_2 dissolves in water. (Section 22.7)

overall reaction order The sum of the reaction orders of all the reactants appearing in the rate expression when the rate can be expressed as $\text{rate} = k[\text{A}]^a[\text{B}]^b \ldots$. (Section 14.3)

overlap The extent to which atomic orbitals on different atoms share the same region of space. When the overlap between two orbitals is large, a strong bond may be formed. (Section 9.4)

oxidation A process in which a substance loses one or more electrons. (Section 4.4)

oxidation number (oxidation state) A positive or negative whole number assigned to an element in a molecule or ion on the basis of a set of formal rules; to some degree it reflects the positive or negative character of that atom. (Section 4.4)

oxidation–reduction (redox) reaction A chemical reaction in which the oxidation states of certain atoms change. (Section 4.4; Chapter 20: Introduction)

oxidizing agent, or oxidant The substance that is reduced and thereby causes the oxidation of some other substance in an oxidation–reduction reaction. (Section 20.1)

oxyacid A compound in which one or more OH groups, and possibly additional oxygen atoms, are bonded to a central atom. (Section 16.10)

oxyanion A polyatomic anion that contains one or more oxygen atoms. (Section 2.8)

ozone The name given to O_3, an allotrope of oxygen. (Section 7.8)

paramagnetism A property that a substance possesses if it contains one or more unpaired electrons. A paramagnetic substance is drawn into a magnetic field. (Section 9.8)

partial pressure The pressure exerted by a particular gas in a mixture. (Section 10.6)

particle accelerator A device that uses strong magnetic and electrostatic fields to accelerate charged particles. (Section 21.3)

parts per billion (ppb) The concentration of a solution in grams of solute per 10^9 (billion) grams of solution; equals micrograms of solute per liter of solution for aqueous solutions. (Section 13.4)

parts per million (ppm) The concentration of a solution in grams of solute per 10^6 (million) grams of solution; equals milligrams of solute per liter of solution for aqueous solutions. (Section 13.4)

pascal (Pa) The SI unit of pressure: $1 \text{ Pa} = 1 \text{ N/m}^2$. (Section 10.2)

Pauli exclusion principle A rule stating that no two electrons in an atom may have the same four quantum numbers (n, l, m_l, and m_s). As a reflection of this principle, there can be no more than two electrons in any one atomic orbital. (Section 6.7)

peptide bond A bond formed between two amino acids. (Section 24.7)

percent ionization The percent of a substance that undergoes ionization on dissolution in water. The term applies to solutions of weak acids and bases. (Section 16.6)

percent yield The ratio of the actual (experimental) yield of a product to its theoretical (calculated) yield, multiplied by 100. (Section 3.7)

period The row of elements that lie in a horizontal row in the periodic table. (Section 2.5)

periodic table The arrangement of elements in order of increasing atomic number, with elements having similar properties placed in vertical columns. (Section 2.5)

petroleum A naturally occurring combustible liquid composed of hundreds of hydrocarbons and other organic compounds. (Section 5.8)

pH The negative log in base 10 of the aquated hydrogen ion concentration: $\text{pH} = -\log[\text{H}^+]$. (Section 16.4)

pH titration curve A graph of pH as a function of added titrant. (Section 17.3)

phase change The conversion of a substance from one state of matter to another. The phase changes we consider are melting and freezing $(\text{solid} \rightleftharpoons \text{liquid})$, sublimation and deposition, and vaporization and condensation $(\text{liquid} \rightleftharpoons \text{gas})$. (Section 11.4)

phase diagram A graphic representation of the equilibria among the solid, liquid, and gaseous phases of a substance as a function of temperature and pressure. (Section 11.6)

phospholipid A form of lipid molecule that contains charged phosphate groups. (Section 24.9)

photochemical smog A complex mixture of undesirable substances produced by the action of sunlight on an urban atmosphere polluted with automobile emissions. The major starting ingredients are nitrogen oxides and organic substances, notably olefins and aldehydes. (Section 18.2)

photodissociation The breaking of a molecule into two or more neutral fragments as a result of absorption of light. (Section 18.2)

photoelectric effect The emission of electrons from a metal surface induced by light. (Section 6.2)

photoionization The removal of an electron from an atom or molecule by absorption of light. (Section 18.2)

photon The smallest increment (a quantum) of radiant energy; a photon of light with frequency ν has an energy equal to $h\nu$. (Section 6.2)

photosynthesis The process that occurs in plant leaves by which light energy is used to convert carbon dioxide and water to carbohydrates and oxygen. (Section 23.3)

physical changes Changes (such as a phase change) that occur with no change in chemical composition. (Section 1.3)

physical properties Properties that can be measured without changing the composition of a substance, for example, color and freezing point. (Section 1.3)

pi (π) bond A covalent bond in which electron density is concentrated above and below the internuclear axis. (Section 9.6)

pi (π) molecular orbital A molecular orbital that concentrates the electron density on opposite sides of an imaginary line that passes through the nuclei. (Section 9.8)

Planck constant (*h*) The constant that relates the energy and frequency of a photon, $E = h\nu$. Its value is 6.626×10^{-34} J-s. (Section 6.2)

plastic A material that can be formed into particular shapes by application of heat and pressure. (Section 12.8)

polar covalent bond A covalent bond in which the electrons are not shared equally. (Section 8.4)

polarizability The ease with which the electron cloud of an atom or a molecule is distorted by an outside influence, thereby inducing a dipole moment. (Section 11.2)

polar molecule A molecule that possesses a nonzero dipole moment. (Section 8.4)

polyatomic ion An electrically charged group of two or more atoms. (Section 2.7)

polydentate ligand A ligand in which two or more donor atoms can coordinate to the same metal ion. (Section 23.3)

polymer A large molecule of high molecular mass, formed by the joining together, or polymerization, of a large number of molecules of low molecular mass. The individual molecules forming the polymer are called monomers. (Sections 12.1 and 12.8)

polypeptide A polymer of amino acids that has a molecular weight of less than 10,000. (Section 24.7)

polyprotic acid A substance capable of dissociating more than one proton in water; H_2SO_4 is an example. (Section 16.6)

polysaccharide A substance made up of many monosaccharide units joined together. (Section 24.8)

porphyrin A complex derived from the porphine molecule. (Section 23.3)

positron A particle with the same mass as an electron but with a positive charge, ${}_{+1}^{0}e$, or β^+. (Section 21.1)

positron emission A nuclear decay process where a positron, a particle with the same mass as an electron but with a positive charge, symbol ${}_{+1}^{0}e$, or β^+ is emitted from the nucleus. (Section 21.1)

potential energy The energy that an object possesses as a result of its composition or its position with respect to another object. (Section 5.1)

precipitate An insoluble substance that forms in, and separates from, a solution. (Section 4.2)

precipitation reaction A reaction that occurs between substances in solution in which one of the products is insoluble. (Section 4.2)

precision The closeness of agreement among several measurements of the same quantity; the reproducibility of a measurement. (Section 1.5)

pressure A measure of the force exerted on a unit area. In chemistry, pressure is often expressed in units of atmospheres (atm) or torr: $760 \text{ torr} = 1 \text{ atm}$; in SI units pressure is expressed in pascals (Pa). (Section 10.2)

pressure–volume (*PV*) work Work performed by expansion of a gas against a resisting pressure. (Section 5.3)

primary cell A voltaic cell that cannot be recharged. (Section 20.7)

primary structure The sequence of amino acids along a protein chain. (Section 24.7)

primitive lattice A crystal lattice in which the lattice points are located only at the corners of each unit cell. (Section 12.2)

probability density (ψ^2) A value that represents the probability that an electron will be found at a given point in space. Also called **electron density**. (Section 6.5)

product A substance produced in a chemical reaction; it appears to the right of the arrow in a chemical equation. (Section 3.1)

property A characteristic that gives a sample of matter its unique identity. (Section 1.1)

protein A biopolymer formed from amino acids. (Section 24.7)

protium The most common isotope of hydrogen. (Section 22.2)

proton A positively charged subatomic particle found in the nucleus of an atom. (Section 2.3)

pure substance Matter that has a fixed composition and distinct properties. (Section 1.2)

pyrometallurgy A process in which heat converts a mineral in an ore from one chemical form to another and eventually to the free metal. (Section 23.2)

qualitative analysis The determination of the presence or absence of a particular substance in a mixture. (Section 17.7)

quantitative analysis The determination of the amount of a given substance that is present in a sample. (Section 17.7)

quantum The smallest increment of radiant energy that may be absorbed or emitted; the magnitude of radiant energy is $h\nu$. (Section 6.2)

quaternary structure The structure of a protein resulting from the clustering of several individual protein chains into a final specific shape. (Section 24.7)

racemic mixture A mixture of equal amounts of the dextrorotatory and levorotatory forms of a chiral molecule. A racemic mixture will not rotate the plane of polarized light. (Section 23.4)

rad A measure of the energy absorbed from radiation by tissue or other biological material; $1 \text{ rad} = \text{transfer of } 1 \times 10^{-2} \text{ J}$ of energy per kilogram of material. (Section 21.9)

radial probability function The probability that the electron will be found at a certain distance from the nucleus. (Section 6.6)

radioactive Possessing **radioactivity**, the spontaneous disintegration of an unstable atomic nucleus with accompanying emission of radiation. (Section 2.2; Chapter 21: Introduction)

radioactive decay chain A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one. Also called **nuclear disintegration series**. (Section 21.2)

radioisotope An isotope that is radioactive; that is, it is undergoing nuclear changes with emission of radiation. (Section 21.1)

radionuclide A radioactive nuclide. (Section 21.1)

radiotracer A radioisotope that can be used to trace the path of an element in a chemical system. (Section 21.5)

Raoult's law A law stating that the partial pressure of a solvent over a solution, P_{solution}, is given by the vapor pressure of the pure solvent, $P^{\circ}_{\text{solvent}}$, times the mole fraction of a solvent in the solution, X_{solvent}: $P_{\text{solution}} = X_{\text{solvent}}P^{\circ}_{\text{solvent}}$. (Section 13.5)

rare earth element See **lanthanide element**. (Sections 6.8 and 6.9)

rate constant A constant of proportionality between the reaction rate and the concentrations of reactants that appear in the rate law. (Section 14.3)

rate-determining step The slowest elementary step in a reaction mechanism. (Section 14.6)

rate law An equation that relates the reaction rate to the concentrations of reactants (and sometimes of products also). (Section 14.3)

reactant A starting substance in a chemical reaction; it appears to the left of the arrow in a chemical equation. (Section 3.1)

reaction mechanism A detailed picture, or model, of how the reaction occurs; that is, the order in which bonds are broken and formed and the changes in relative positions of the atoms as the reaction proceeds. (Section 14.6)

reaction order The power to which the concentration of a reactant is raised in a rate law. (Section 14.3)

reaction quotient (*Q*) The value that is obtained when concentrations of reactants and products are inserted into the equilibrium expression. If the concentrations are equilibrium concentrations, $Q = K$; otherwise, $Q \neq K$. (Section 15.6)

reaction rate A measure of the decrease in concentration of a reactant or the increase in concentration of a product with time. (Section 14.2)

redox (oxidation–reduction) reaction A reaction in which certain atoms undergo changes in oxidation states. The substance increasing in oxidation state is oxidized; the substance decreasing in oxidation state is reduced. (Section 4.4; Chapter 20: Introduction)

reducing agent, or reductant The substance that is oxidized and thereby causes the reduction of some other substance in an oxidation–reduction reaction. (Section 20.1)

reduction A process in which a substance gains one or more electrons. (Section 4.4)

rem A measure of the biological damage caused by radiation; $\text{rems} = \text{rads} \times \text{RBE}$. (Section 21.9)

renewable energy sources Energy such as solar energy, wind energy, and hydroelectric energy derived from essentially inexhaustible sources. (Section 5.8)

representative (main-group) element An element from within the s and p blocks of the periodic table (Figure 6.29). (Section 6.9)

resonance structures (resonance forms) Individual Lewis structures in cases where two or more Lewis structures are equally good descriptions of a single molecule. The resonance structures in such an instance are "averaged" to give a more accurate description of the real molecule. (Section 8.6)

reverse osmosis The process by which water molecules move under high pressure through a semipermeable membrane from the more concentrated to the less concentrated solution. (Section 18.4)

reversible process A process that can go back and forth between states along exactly the same path; a system at equilibrium is reversible if equilibrium can be shifted by an infinitesimal modification of a variable such as temperature. (Section 19.1)

ribonucleic acid (RNA) A polynucleotide in which ribose is the sugar component. (Section 24.10)

root-mean-square (rms) speed (μ) The square root of the average of the squared speeds of the gas molecules in a gas sample. (Section 10.7)

rotational motion Movement of a molecule as though it is spinning like a top. (Section 19.3)

salinity A measure of the salt content of seawater, brine, or brackish water. It is equal to the mass in grams of dissolved salts present in 1 kg of seawater. (Section 18.3)

salt An ionic compound formed by replacing one or more hydrogens of an acid by other cations. (Section 4.3)

saponification Hydrolysis of an ester in the presence of a base. (Section 24.4)

saturated solution A solution in which undissolved solute and dissolved solute are in equilibrium. (Section 13.2)

scientific law A concise verbal statement or a mathematical equation that summarizes a wide range of observations and experiences. (Section 1.3)

scientific method The general process of advancing scientific knowledge by making experimental observations and by formulating hypotheses, theories, and laws. (Section 1.3)

secondary cell A voltaic cell that can be recharged. (Section 20.7)

secondary structure The manner in which a protein is coiled or stretched. (Section 24.7)

second law of thermodynamics A statement of our experience that there is a direction to the way events occur in nature. When a process occurs spontaneously in one direction, it is nonspontaneous in the reverse direction. It is possible to state the second law in many different forms, but they all relate back to the same idea about spontaneity. One of the most common statements found in chemical contexts is that in any spontaneous process the entropy of the universe increases. (Section 19.2)

second-order reaction A reaction in which the overall reaction order (the sum of the concentration-term exponents) in the rate law is 2. (Section 14.4)

semiconductor A material that has electrical conductivity between that of a metal and that of an insulator. (Section 12.7)

sigma (σ) bond A covalent bond in which electron density is concentrated along the internuclear axis. (Section 9.6)

sigma (σ) molecular orbital A molecular orbital that centers the electron density about an imaginary line passing through two nuclei. (Section 9.7)

significant figures The digits that indicate the precision with which a measurement is made; all digits of a measured quantity are significant, including the last digit, which is uncertain. (Section 1.5)

silica Common name for silicon dioxide. (Section 22.4)

silicates Compounds containing silicon and oxygen, structurally based on SiO_4 tetrahedra. (Section 22.10)

single bond A covalent bond involving one electron pair. (Section 8.3)

SI units The preferred metric units for use in science. (Section 1.4)

smectic liquid crystalline phase A liquid crystal in which the molecules are aligned along their long axes and arranged in sheets, with the ends of the molecules aligned. There are several different kinds of smectic phases. (Section 12.8)

solid Matter that has both a definite shape and a definite volume. (Section 1.2)

solubility The amount of a substance that dissolves in a given quantity of solvent at a given temperature to form a saturated solution. (Sections 4.2 and 13.2)

solubility-product constant (solubility product) (K_{sp}) An equilibrium constant related to the equilibrium between a solid salt and its ions in solution. It provides a quantitative measure of the solubility of a slightly soluble salt. (Section 17.4)

solute A substance dissolved in a solvent to form a solution; it is normally the component of a solution present in the smaller amount. (Section 4.1)

solution A mixture of substances that has a uniform composition; a homogeneous mixture. (Section 1.2)

solution alloy A homogeneous alloy, where two or more elements are distributed randomly and uniformly throughout the solid. (Section 12.3)

solvation The clustering of solvent molecules around a solute particle. (Section 13.1)

solvent The dissolving medium of a solution; it is normally the component of a solution present in the greater amount. (Section 4.1)

specific heat (C_s) The heat capacity of 1 g of a substance; the heat required to raise the temperature of 1 g of a substance by 1 °C. (Section 5.5)

spectator ions Ions that go through a reaction unchanged and that appear on both sides of the complete ionic equation. (Section 4.2)

spectrochemical series A list of ligands arranged in order of their abilities to split the *d*-orbital energies (using the terminology of the crystal-field model). (Section 23.6)

spectrum The distribution among various wavelengths of the radiant energy emitted or absorbed by an object. (Section 6.3)

spin magnetic quantum number (m_s) A quantum number associated with the electron spin; it may have values of $+\frac{1}{2}$ or $-\frac{1}{2}$. (Section 6.7)

spin-pairing energy The energy required to pair an electron with another electron occupying an orbital. (Section 23.6)

spontaneous process A process that is capable of proceeding in a given direction, as written or described, without needing to be driven by an outside source of energy. A process may be spontaneous even though it is very slow. (Section 19.1)

standard atmospheric pressure Defined as 760 torr or, in SI units, 101.325 kPa. (Section 10.2)

standard emf, also called the standard cell potential ($E°$) The emf of a cell when all reagents are at standard conditions. (Section 20.4)

standard enthalpy change ($\Delta H°$) The change in enthalpy in a process when all reactants and products are in their stable forms at 1 atm pressure and a specified temperature, commonly 25 °C. (Section 5.7)

standard enthalpy of formation ($\Delta H_f°$) The change in enthalpy that accompanies the formation of one mole of a substance from its elements, with all substances in their standard states. (Section 5.7)

standard free energy of formation ($\Delta G_f°$) The change in free energy associated with the formation of a substance from its elements under standard conditions. (Section 19.5)

standard hydrogen electrode (SHE) An electrode based on the half-reaction $2\,H^+(1\,M) + 2\,e^- \longrightarrow H_2(1\,atm)$. The standard electrode potential of the standard hydrogen electrode is defined as 0 V. (Section 20.4)

standard molar entropy ($S°$) The entropy value for a mole of a substance in its standard state. (Section 19.4)

standard reduction potential ($E°_{red}$) The potential of a reduction half-reaction under standard conditions, measured relative to the standard hydrogen electrode. A standard reduction potential is also called a standard electrode potential. (Section 20.4)

standard solution A solution of known concentration. (Section 4.6)

standard temperature and pressure (STP) Defined as 0 °C and 1 atm pressure; frequently used as reference conditions for a gas. (Section 10.4)

starch The general name given to a group of polysaccharides that acts as energy-storage substances in plants. (Section 24.8)

state function A property of a system that is determined by its state or condition and not by how it got to that state; its value is fixed when temperature, pressure, composition, and physical form are specified; *P, V, T, E,* and *H* are state functions. (Section 5.2)

states of matter The three forms that matter can assume: solid, liquid, and gas. (Section 1.2)

stereoisomers Compounds possessing the same formula and bonding arrangement but differing in the spatial arrangements of the atoms. (Section 23.4)

stoichiometry The relationships among the quantities of reactants and products involved in chemical reactions. (Chapter 3: Introduction)

stratosphere The region of the atmosphere directly above the troposphere. (Section 18.1)

strong acid An acid that ionizes completely in water. (Section 4.3)

strong base A base that ionizes completely in water. (Section 4.3)

strong electrolyte A substance (strong acids, strong bases, and most salts) that is completely ionized in solution. (Section 4.1)

structural formula A formula that shows not only the number and kinds of atoms in the molecule but also the arrangement (connections) of the atoms. (Section 2.6)

structural isomers Compounds possessing the same formula but differing in the bonding arrangements of the atoms. (Sections 23.4 and 24.2)

subatomic particles Particles such as protons, neutrons, and electrons that are smaller than an atom. (Section 2.2)

subshell One or more orbitals with the same set of quantum numbers *n* and *l*. For example, we speak of the 2*p* subshell ($n = 2, l = 1$), which is composed of three orbitals ($2p_x$, $2p_y$, and $2p_z$). (Section 6.5)

substitutional alloy A homogeneous (solution) alloy in which atoms of different elements randomly occupy sites in the lattice. (Section 23.6)

substitution reactions Reactions in which one atom (or group of atoms) replaces another atom (or group) within a molecule; substitution reactions are typical for alkanes and aromatic hydrocarbons. (Section 24.3)

substrate A substance that undergoes a reaction at the active site in an enzyme. (Section 14.7)

supercritical mass An amount of fissionable material larger than the critical mass. (Section 21.7)

supersaturated solution A solution containing more solute than an equivalent saturated solution. (Section 13.2)

surface tension The intermolecular, cohesive attraction that causes a liquid to minimize its surface area. (Section 11.3)

surroundings In thermodynamics, everything that lies outside the system that we study. (Section 5.1)

system In thermodynamics, the portion of the universe that we single out for study. We must be careful to state exactly what the system contains and what transfers of energy it may have with its surroundings. (Section 5.1)

termolecular reaction An elementary reaction that involves three molecules. Termolecular reactions are rare. (Section 14.6)

tertiary structure The overall shape of a large protein, specifically, the manner in which sections of the protein fold back upon themselves or intertwine. (Section 24.7)

theoretical yield The quantity of product that is calculated to form when all of the limiting reagent reacts. (Section 3.7)

theory A tested model or explanation that satisfactorily accounts for a certain set of phenomena. (Section 1.3)

thermochemistry The relationship between chemical reactions and energy changes. (Chapter 5: Introduction)

thermodynamics The study of energy and its transformation. (Chapter 5: Introduction)

thermonuclear reaction Another name for fusion reactions; reactions in which two light nuclei are joined to form a more massive one. (Section 21.8)

thermoplastic A polymeric material that can be readily reshaped by application of heat and pressure. (Section 12.8)

thermosetting plastic A plastic that, once formed in a particular mold, is not readily reshaped by application of heat and pressure. (Section 12.8)

third law of thermodynamics A law stating that the entropy of a pure, crystalline solid at absolute zero temperature is zero: $S(0\text{ K}) = 0$. (Section 19.3)

titration The process of reacting a solution of unknown concentration with one of known concentration (a standard solution). (Section 4.6)

torr A unit of pressure ($1\text{ torr} = 1\text{ mm Hg}$). (Section 10.2)

transition elements (transition metals) Elements in which the *d* orbitals are partially occupied. (Section 6.8)

transition state (activated complex) The particular arrangement of reactant and product molecules at the point of maximum energy in the rate-determining step of a reaction. (Section 14.5)

translational motion Movement in which an entire molecule moves in a definite direction. (Section 19.3)

transuranium elements Elements that follow uranium in the periodic table. (Section 21.3)

triple bond A covalent bond involving three electron pairs. (Section 8.3)

triple point The temperature at which solid, liquid, and gas phases coexist in equilibrium. (Section 11.6)

tritium The isotope of hydrogen whose nucleus contains a proton and two neutrons. (Section 22.2)

troposphere The region of Earth's atmosphere extending from the surface to about 12 km altitude. (Section 18.1)

Tyndall effect The scattering of a beam of visible light by the particles in a colloidal dispersion. (Section 13.6)

uncertainty principle A principle stating there is an inherent uncertainty in the precision with which we can simultaneously specify the position and momentum of a particle. This uncertainty is significant only for particles of extremely small mass, such as electrons. (Section 6.4)

unimolecular reaction An elementary reaction that involves a single molecule. (Section 14.6)

unit cell The smallest portion of a crystal that reproduces the structure of the entire crystal when repeated in different directions in space. It is the repeating unit or building block of the crystal lattice. (Section 12.2)

unsaturated solution A solution containing less solute than a saturated solution. (Section 13.2)

valence band A band of closely spaced molecular orbitals that is essentially fully occupied by electrons. (Section 12.7)

valence-bond theory A model of chemical bonding in which an electron-pair bond is formed between two atoms by the overlap of orbitals on the two atoms. (Section 9.4)

valence electrons The outermost electrons of an atom; those that occupy orbitals not occupied in the nearest noble-gas element of lower atomic number. The valence electrons are the ones the atom uses in bonding. (Section 6.8)

valence orbitals Orbitals that contain the outer-shell electrons of an atom. (Chapter 7: Introduction)

valence-shell electron-pair repulsion (VSEPR) model A model that accounts for the geometric arrangements of shared and unshared electron pairs around a central atom in terms of the repulsions between electron pairs. (Section 9.2)

van der Waals equation An equation of state for nonideal gases that is based on adding corrections to the ideal-gas equation. The correction terms account for intermolecular forces of attraction and for the volumes occupied by the gas molecules themselves. (Section 10.9)

vapor Gaseous state of any substance that normally exists as a liquid or solid. (Section 10.1)

vapor pressure The pressure exerted by a vapor in equilibrium with its liquid or solid phase. (Section 11.5)

vibrational motion Movement of the atoms within a molecule in which they move periodically toward and away from one another. (Section 19.3)

viscosity A measure of the resistance of fluids to flow. (Section 11.3)

volatile Tending to evaporate readily. (Section 11.5)

voltaic (galvanic) cell A device in which a spontaneous oxidation–reduction reaction occurs with the passage of electrons through an external circuit. (Section 20.3)

vulcanization The process of cross-linking polymer chains in rubber. (Section 12.6)

watt A unit of power; $1\text{ W} = 1\text{ J/s}$. (Section 20.5)

wave function A mathematical description of an allowed energy state (an orbital) for an electron in the quantum mechanical model of the atom; it is usually symbolized by the Greek letter ψ. (Section 6.5)

wavelength The distance between identical points on successive waves. (Section 6.1)

weak acid An acid that only partly ionizes in water. (Section 4.3)

weak base A base that only partly ionizes in water. (Section 4.3)

weak electrolyte A substance that only partly ionizes in solution. (Section 4.1)

work The movement of an object against some force. (Section 5.1)

INDEX

Note: Page references followed by *n* indicate contents available in endnotes. Page references followed by *f* indicate contents available in figures.

AB_n molecules, 345–46, 347, 349, 354, 357
Absolute entropy, 828
Absolute temperature, 419, 596
Absolute zero, 406
Absorption, 560–61, 608
Absorption spectrum, 1020
Accident prevention, safer chemistry for, 799
Accuracy, 22
Acetaldehyde (ethanal), 572, 1059, 1061, 1062
  properties of, 449
Acetaminophen, 1089
Acetate ion, 66
Acetic acid (ethanoic acid), 133, 687, 709, 722, 726, 1059, 1062
  carbonylation of, 852
  decarbonylation of, 850
  in green chemistry, 800
  hydrogen bonding in, 453–54
  ionization of, 127
  production of, 852, 1063
  properties of, 687
  pure (glacial acetic acid), 160
  shape of, 355
  titration with caustic soda (NaOH), 740–44
Acetic anhydride, 1087
Acetone (propanone), 158, 473, 475, 478, 538, 568, 573, 1059, 1061, 1062
Acetonitrile, 448, 569, 571, 591, 618, 1042
  methyl isonitrate converted to, 589, 595–96, 618
  properties of, 449
Acetylene, 190, 210, 340–41, 850, 983, 1044, 1053, 1059
  production of, 436
  standard enthalpy of formation for, 190
  triple bonds in, 368
Acetylide ion, 983
Acetylsalicylic acid (aspirin), 4, 119, 392, 719, 773, 1062
Acid-base equilibria, 670–723. *See also* Aqueous equilibria
  acid-dissociation constant and base dissociation constant relationship, 699–701
  Arrhenius definitions, 672
  autoionization of water, 678–80
  Brønsted-Lowry acids and bases, 673–78
  conjugate acid-base pairs, 674–76
    H^+ ions in water and, 673
    proton-transfer reactions, 673–74
    relative strengths of, 676–78
  chemical structure and, 705–10
    binary acids, 706
    carboxylic acids, 709–10
    factors affecting acid strength, 705–6
    oxyacids, 707–8
  ion product, 679–80
  Lewis acids and bases, 710–13
    electron-pair acceptor/donor concept, 710–11
    metal ions and, 711
  pH scale, 680–84
    measuring, 683–84
    other "p" scales, 682–83
  of salt solutions, 702–5
    anion reaction with water, 702
    cation reaction with water, 702–4
    combined cation-anion effect, 704–5
  solubility equilibria and, 751
  strong acids and bases, 684–85
    in buffered solutions, 735–37
  types of, 698–99
  weak acids and bases, 686–96, 699–701
    acid-dissociation constant, 686–87, 690–92
    common-ion effect on, 726–28
    percent ionization of, 689
    polyprotic acids, 694–96
Acid-base indicators, 153–54, 683–84
Acid-base properties, of organic substances, 1043
Acid-base reactions, 132–38. *See also* Acid-base equilibria

  ionic properties of, 132–33
  Lewis, 710–13
  metal oxides reacting with, 275
  monoprotic, 133, 684
  names and formulas of, 67–68
  oxidation of metals by, 142–43
  oxyacids, 707–8, 966
  properties of, 132–33
  reactions of (*See also* Acid-base reactions)
    with alcohol, 666
    with magnesium, 142
    with magnesium hydroxide, 136, 137
  relating to anions, 67
  relative strengths of, 676–78
  strong, 133–34, 676, 677, 684–85
    in buffered solutions, 735–37
    titration with weak base, 745–46
  titrating, 152–54
  weak, 133–34, 676, 677, 686–96, 699–701
    acid-dissociation constant (K_a), 686–87, 690–92
    common-ion effect on, 726–28
    percent ionization of, 689
    polyprotic, 694–96, 746–47
Acid salts, 701
Acid spills, 138
Actinides, electron configurations of, 240–41
Activated complex (transition state), 595, 600
Activation, entropy of, 853
Activation energy, 594–95
  catalysis and, 608, 611, 657
  determining, 597–99
Active metals, 143
Active site, 611
Activity, 923
Activity series, 143–45, 877
Actual yield, 109–10
Addition, significant figures in, 25
Addition polymerization, 509
Addition polymers, 510
Addition reactions
  of alkenes and alkynes, 1054–56
  mechanism of, 1055–56
Adenine, 477, 1079, 1080
Adenosine diphosphate (ADP), 842, 853, 979
  conversion of ATP to, 842
  lower-energy, 842
Adenosine monophosphate (AMP), 1090
Adenosine triphosphate (ATP), 842, 853, 979
  conversion of ADP to, 842
  higher-energy, 842
Adhesive forces, 456
Adipic acid, 109–10, 511

ADP (adenosine diphosphate), 842, 853, 979
  conversion of ATP to, 842
  lower-energy, 842
Adrenaline (epinephrine), 116, 570
Adsorption, 560, 608
Advanced burning, 939
Air, 120
  combustion in, 89
  composition of, 400
  density of, 20
Air bags, automobile, 88, 415
Air pollution, 610
  in Mexico City, 805
Alanine, 709, 1069
Alanylglycylserine, 1070
Alcohol(s), 70–71, 538, 1058–61
  condensation reactions with, 1063
  as functional groups, 1060
  oxidation of, 1062
  reaction of organic acid with, 666
  solubilities of, 539
Aldehydes, 1061–62
Alizarin yellow R, 684
Alkali chlorides, lattice energies of, 304
Alkali metal halides, properties of, 498
Alkali metal ions, 763
Alkali (group 1A) metals, 54, 143, 238, 240, 241, 278–81
  condensed electron configurations of, 240
  group trends for, 278–81
  in ionic hydrides, 959
  ionic hydroxides of, 685–86
  oxidation number of, 141
  as reducing agent, 874
Alkaline battery, 887
Alkaline earth (group 2A) metals, 54, 143, 241, 281–82
  group trends for, 281–82
  in ionic hydrides, 959
  ionic hydroxides of, 685–86
  oxidation number of, 141
  as reducing agent, 874
Alkalosis, 737
Alkanes, 69, 1044, 1045–49
  cycloalkanes, 1049

    - of polyprotic acids, 746–47
    - strong, 738–40
    - weak, 740–44
  - equivalence point of, 152
- TNT (trinitrotoluene), 330, 976
- Tokamak, 938
- Toluene (methylbenzene), 116, 502, 548, 550, 569, 570, 800, 1056
- Tooth decay, 748, 755
- Tooth enamel, 748, 755, 772
- Torr, 402
- Torricelli, Evangelista, 402–3
- Trace elements, 61
- *trans* fats, 1076
- Transferrin, 1011–12
- *trans* isomers, 1003–4, 1015, 1016
- Transition-metal complexes, 1002–7
- Transition-metal ions, 306
  - aqueous solutions of, 1000
- Transition-metal oxides, 610
- Transition metals, 63, 998–1002
  - chromium, 1002
  - compounds of (*See* Coordination compounds)
  - copper (*See* Copper (Cu))
  - electron configurations of, 240, 999–1001
  - iron (*See* Iron (Fe))
  - magnetism, 1001–2
  - mineral sources of, 998
  - oxidation states of, 999–1001
  - physical properties of, 998–99
  - position in periodic table, 998
  - radii of, 999
- Transition state (activated complex), 595, 600
- Translational motion, 824
- Transplatin, 394
- Transuranium elements, 920
- Triazine, 339
- Triclinic lattice, 484
- Trigonal bipyramidal geometry, 345, 352, 353, 357, 1036
- Trigonal planar geometry, 345–46, 347, 348, 350, 357, 366, 1042
- Trigonal pyramidal geometry, 345–46, 349, 350
- Trihalomethanes (THMs), 797–98, 807
- Trimethylamine, 1066
- 2,2,4-Trimethylpentane, 1050
- 2,3,4-Trimethylpentane, 208
- Trinitroglycerin, 199–200. *See also* Nitroglycerin
- Trinitrotoluene (TNT), 330, 976
- Trinity test, 934
- Triphosphate ion, 1008
- Triple-alpha process, 939
- Triple bonds, 308, 1042
  - hybrid orbitals and, 368
  - length of, 329

- Triple point, 465
- *tri-* prefix, 68
- Tristearin, 195
- Tritium, 74, 957
- Tropopause, 776
- Troposphere, 776
- Troposphere-to-stratosphere diffusion rates, 783
- Trouton's rule, 852
- Tryptophan, 1069
- T-shaped geometry, 345, 353
- Tumor, malignant, 943
- Tums, 139
- Tungsten, 274, 292
- Tungsten carbide, 984
- Turnover number, 611
- Tyndall effect, 560
- Tyrosine, 1069

[a] The labels on top (1A, 2A, etc.) are common American usage. The labels below these (1, 2, etc.) are those recommended by the International Union of Pure and Applied Chemistry (IUPAC).

Except for elements 114 and 116, the names and symbols for elements above 113 have not yet been decided.

Atomic weights in brackets are the names of the longest-lived or most important isotope of radioactive elements.

Further information is available at http://www.webelements.com

** Discovered in 2010, element 117 is currently under review by IUPAC.

List of Elements with Their Symbols and Atomic Weights

Element	Symbol	Atomic Number	Atomic Weight
Actinium	Ac	89	227.03[a]
Aluminum	Al	13	26.981538
Americium	Am	95	243.06[a]
Antimony	Sb	51	121.760
Argon	Ar	18	39.948
Arsenic	As	33	74.92160
Astatine	At	85	209.99[a]
Barium	Ba	56	137.327
Berkelium	Bk	97	247.07[a]
Beryllium	Be	4	9.012183
Bismuth	Bi	83	208.98038
Bohrium	Bh	107	264.12[a]
Boron	B	5	10.81
Bromine	Br	35	79.904
Cadmium	Cd	48	112.414
Calcium	Ca	20	40.078
Californium	Cf	98	251.08[a]
Carbon	C	6	12.0107

*[b]		115	288[a]
*[b]		117	294[a]
*[b]		118	294[a]

[a] Mass of longest-lived or most important isotope.

[b] Except for elements 114 and 116, the names and symbols for elements above 113 have not yet been decided.

Common Ions

Positive Ions (Cations)

1+

ammonium (NH_4^+)
cesium (Cs^+)
copper(I) or cuprous (Cu^+)
hydrogen (H^+)
lithium (Li^+)
potassium (K^+)
silver (Ag^+)
sodium (Na^+)

2+

barium (Ba^{2+})
cadmium (Cd^{2+})
calcium (Ca^{2+})
chromium(II) or chromous (Cr^{2+})
cobalt(II) or cobaltous (Co^{2+})
copper(II) or cupric (Cu^{2+})
iron(II) or ferrous (Fe^{2+})
lead(II) or plumbous (Pb^{2+})
magnesium (Mg^{2+})
manganese(II) or manganous (Mn^{2+})
mercury(I) or mercurous (Hg_2^{2+})
mercury(II) or mercuric (Hg^{2+})
strontium (Sr^{2+})
nickel(II) (Ni^{2+})
tin(II) or stannous (Sn^{2+})
zinc (Zn^{2+})

3+

aluminum (Al^{3+})
chromium(III) or chromic (Cr^{3+})
iron(III) or ferric (Fe^{3+})

Negative Ions (Anions)

1−

acetate (CH_3COO^- or $C_2H_3O_2^-$)
bromide (Br^-)
chlorate (ClO_3^-)
chloride (Cl^-)
cyanide (CN^-)
dihydrogen phosphate ($H_2PO_4^-$)
fluoride (F^-)
hydride (H^-)
hydrogen carbonate or bicarbonate (HCO_3^-)
hydrogen sulfite or bisulfite (HSO_3^-)
hydroxide (OH^-)
iodide (I^-)
nitrate (NO_3^-)
nitrite (NO_2^-)
perchlorate (ClO_4^-)
permanganate (MnO_4^-)
thiocyanate (SCN^-)

2−

carbonate (CO_3^{2-})
chromate (CrO_4^{2-})
dichromate ($Cr_2O_7^{2-}$)
hydrogen phosphate (HPO_4^{2-})
oxide (O^{2-})
peroxide (O_2^{2-})
sulfate (SO_4^{2-})
sulfide (S^{2-})
sulfite (SO_3^{2-})

3−

arsenate (AsO_4^{3-})
phosphate (PO_4^{3-})

Fundamental Constants[*]

Atomic mass unit	1 amu	$= 1.660538921 \times 10^{-27}$kg
	1 g	$= 6.02214165 \times 10^{23}$ amu
Avogadro's number[†]	N_A	$= 6.02214129 \times 10^{23}$/mol
Boltzmann Constant	k	$= 1.3806488 \times 10^{-23}$J/K
Electron charge	e	$= 1.602176565 \times 10^{-19}$ C
Faraday constant	$\mathcal{F}$	$= 9.64853365 \times 10^{4}$ C/mol
Gas constant	R	= 0.0820582 L-atm/mol-K
		= 8.3144621 J/mol-K
Mass of electron	m_e	$= 5.4857990946 \times 10^{-4}$ amu
		$= 9.10938291 \times 10^{-31}$ kg
Mass of neutron	m_n	= 1.008664916 amu
		$= 1.674927351 \times 10^{-27}$ kg
Mass of proton	m_p	= 1.007276466 amu
		$= 1.672621777 \times 10^{-27}$ kg
Pi	π	= 3.1415927
Planck constant	h	$= 6.62606957 \times 10^{-34}$ J-s
Speed of light in vacuum	c	$= 2.99792458 \times 10^{8}$ m/s

[*] Fundamental constants are listed at the National Institute of Standards and Technology (NIST) Web site: http://physics.nist.gov/cuu/Constants/index.html

[†] Avogadro's number is also referred to as the Avogadro constant. The latter term is the name adopted by agencies such as the International Union of Pure and Applied Chemistry (IUPAC) and the National Institute of Standards and Technology (NIST), but "Avogadro's number" remains in widespread usage and is used in most places in this book.

Useful Conversion Factors and Relationships

Length

SI unit: meter (m)

1 km = 0.62137 mi
1 mi = 5280 ft
= 1.6093 km
1 m = 1.0936 yd
1 in. = 2.54 cm (exactly)
1 cm = 0.39370 in.
1 Å = 10^{-10} m

Mass

SI unit: kilogram (kg)

1 kg = 2.2046 lb
1 lb = 453.59 g
= 16 oz
1 amu = $1.660538921 \times 10^{-27}$ kg

Temperature

SI unit: Kelvin (K)

0 K = −273.15 °C
= −459.67 °F
K = °C + 273.15
$°\text{C} = \frac{5}{9}(°\text{F} - 32°)$
$°\text{F} = \frac{9}{5}°\text{C} + 32°$

Energy (derived)

SI unit: Joule (J)

1 J = 1 kg-m^2/s^2
= 0.2390 cal
= 1C-V
1 cal = 4.184 J
1 eV = 1.602×10^{-19}J

Pressure (derived)

SI unit: Pascal (Pa)

1 Pa = 1 N/m^2
= 1 kg/m-s^2
1 atm = 1.01325×10^5Pa
= 760 torr
= 14.70 lb/in^2
1 bar = 10^5 Pa
1 torr = 1 mm Hg

Volume (derived)

SI unit: cubic meter (m^3)

1 L = 10^{-3} m^3
= 1 dm^3
= 10^3 cm^3
= 1.0567 qt
1 gal = 4 qt
= 3.7854 L
1 cm^3 = 1 mL
1 in^3 = 16.4 cm^3
